

## A Proofs of the XMM Operational Semantics Properties

**Definition 16.** Let  $G$  and  $G'$  be two execution graphs, such that  $G$  is a prefix of  $G'$ . Let  $e$  be an event from  $G'.E$ .

A delta-graph  $\Delta_e G$  is a graph, such that:

- $\Delta_e G.E \triangleq G.E \cup \{e\}$
- $\Delta_e G.\text{lab} \triangleq G.\text{lab}[e \mapsto G'.\text{lab}(e)]$
- $\Delta_e G.\text{po} \triangleq [\Delta_e G.E]; G'.\text{po}; [\Delta_e G.E]$
- $\Delta_e G.\text{rf} \triangleq [\Delta_e G.E]; G'.\text{rf}; [\Delta_e G.E]$
- $\Delta_e G.\text{mo} \triangleq [\Delta_e G.E]; G'.\text{mo}; [\Delta_e G.E]$
- $\Delta_e G.\text{rmw} \triangleq [\Delta_e G.E]; G'.\text{rmw}; [\Delta_e G.E]$

Essentially we construct it by adding  $e$  to  $G$  and all the accompanying edges from  $G'$ .

**Lemma 5.** Let  $G$  and  $G'$  be two execution graphs, such that  $G$  is a prefix of  $G'$ :  $G'|_{G.E} = G$ . Let  $C \subseteq G'.E$  be a subset of committed events. Let  $e$  be an event such that:

- $e \notin G.E$
- $e \in G'.E$
- $e \in G'.R$  implies  $e \in \text{codom}([G.E]; G'.\text{rf}) \cup C$

Finally, assume  $\text{WellFormed}(G, G', C)$  and  $\text{WellFormed}(G')$  hold. Then

$$\langle G', C \rangle \vdash G \xRightarrow{\langle e, \ell \rangle} \Delta_e G \quad \text{where } \ell = G'.\text{lab}(e)$$

PROOF. From  $\text{WellFormed}(G')$  it is obvious, that:

- $\Delta_e G.E = G.E \uplus \{e\}$
- $\Delta_e G.\text{lab} = G.\text{lab}[e \mapsto G'.\text{lab}(e)]$
- $\Delta_e G.\text{po} = G.\text{po} \cup \Delta_{\text{po}}(G, e)$
- $\Delta_e G.\text{mo} = G.\text{mo} \cup \Delta_{\text{mo}}(G, W_1, W_2, e)$
- $\Delta_e G.\text{rmw} = G.\text{rmw} \cup \Delta_{\text{rmw}}(G, r, e)$

The only tricky part is the delta for  $\text{rf}$ . We consider two cases:

- $e \in W$

The following is obvious by definition of  $\Delta_e G$ :

$$\Delta_e G.\text{rf} = G.\text{rf} \cup \Delta_{\text{rf}}^W(G, R, e)$$

- $e \in R$

We have  $e \in \text{codom}([G.E]; G'.\text{rf}) \cup C$ . From this we immediately get that

$$\Delta_e G.\text{rf} = G.\text{rf} \cup \Delta_{\text{rf}}^R(G, w, e)$$

It is also obvious that the resulting configuration is well-formed.  $\square$

**Lemma.** (Proof of Lemma 1)

Let  $G$  and  $G'$  be two execution graphs, such that  $G$  is a prefix of  $G'$ :  $G'|_{G.E} = G$ . Let  $C \subseteq G'.E$  be a subset of committed events,  $\mathcal{U} \triangleq G'.E \setminus C$  be a subset of uncommitted events, and  $\Delta = G'.E \setminus G.E$  be a difference of the two event sets. Moreover, assume  $\text{WellFormed}(G, G', C)$  and  $\text{WellFormed}(G')$  hold.

Let  $\ell \triangleq [e_1, \dots, e_n]$  be an enumeration of a set  $\Delta$ , such that the following conditions are met:

- $\langle e_i, e_j \rangle \in G'.\text{po}$  implies  $i < j$ ;
- $\langle e_i, e_j \rangle \in G'.\text{rf}; [\mathcal{U}]$  implies  $i < j$ ;
- $\forall r \in R \cap \Delta. \exists w \in G.W \cup \Delta. \langle w, r \rangle \in G'.\text{rf}$ .

In other words

- $G'.\text{po}$  and  $G'.\text{rf}; [\mathcal{U}]$  respect the order induced by  $\ell$
- $G'$  is **rf**-complete

Then, the graph  $G'$  can be constructed from  $G$ :

$$\langle G', C \rangle \vdash G \xRightarrow{\ell}^* G'$$

PROOF. The proof will proceed with induction by  $\ell$ .

- Base: when  $\ell$  is empty,  $\Delta$  is empty too. Which means that  $G' = G$ . This immediately implies

$$\langle G', C \rangle \vdash G \xRightarrow{\ell}^* G'$$

- Step: we have  $\ell = [e_1, e_2, \dots, e_n]$ .  
We will now show the following

$$\langle G', C \rangle \vdash G \xRightarrow{\langle e_1, \ell^* \rangle} \Delta_{e_1} G \xRightarrow{\ell'}^* G' \quad \text{where } \ell^* = G'.\text{lab}(e_1), \ell' = [e_2, \dots, e_n]$$

From the assumptions, it is easy to show the following, which proves the first step

$$e_1 \in G'.R \text{ implies } e_1 \in \text{codom}([G.E]; G'.\text{rf}) \cup C$$

The second step is proved by applying the induction hypothesis with  $G \triangleq \Delta_{e_1} G$  and  $\ell \triangleq \ell'$ .  
All other conditions still hold, because we removed the first element of the list.

□

**Corollary 1.** Given graphs  $G, G'$ , committed events  $C \subseteq G'.E$ , and a subset of determined events  $\mathcal{D}$ , such that  $\mathcal{D} \subseteq f \uparrow C$  and  $\text{dom}(G.\text{po}; [\mathcal{D}]) \subseteq \mathcal{D}$ , re-execution can proceed from a graph restricted to  $\mathcal{D}$  if and only if it can proceed from an initial graph:

$$\langle G', C \rangle \vdash G|_{\mathcal{D}} \xRightarrow{*} G' \iff \langle G', C \rangle \vdash G_{\text{init}} \xRightarrow{*} G'$$

PROOF. Follows directly from Lemma 1 and the fact that the set of determined events is a program order closed subset of committed events — meaning that determined reads are not subject to **rf**;  $[\mathcal{U}]$  constraint and thus can be added to the graph at any point during re-execution. □

**Lemma.** (Proof of Lemma 2)

Let  $G, G', C, \mathcal{U}, \Delta, \ell$  be defined similarly as in Lemma 1. In particular, we have that  $\text{WellFormed}(G, G', C)$  and  $\text{WellFormed}(G')$  hold. Moreover, suppose the predicate  $\text{ThreadOrderedUEvents}(G', C, \prec_{\text{tid}})$  holds, restricting uncommitted events for a given  $\prec_{\text{tid}}$  relation.

Then, the list of events  $\ell$  can be reordered and grouped by threads according to  $\prec_{\text{tid}}$  relation:

$$\ell' \triangleq \ell_{t_{i_1}} \cdot \dots \cdot \ell_{t_{i_m}} \quad | \quad k < m \implies t_{i_k} \prec_{\text{tid}} t_{i_m}$$

Where  $\ell_{t_{i_k}}$  is a sublist of  $\ell$ , which contains only the events with  $\text{tid } t_{i_k}$ . In other words

$$\ell' \text{ is ordered by } G'.\text{tid} \downarrow \prec_{\text{tid}} \cup G'.\text{po}$$

and the resulting list  $\ell'$  can still be used to re-execute the graph leading to the same result:

$$\langle G', C \rangle \vdash G \xRightarrow{\ell}^* G' \quad \text{if and only if} \quad \langle G', C \rangle \vdash G \xRightarrow{\ell'}^* G'.$$

PROOF. With all the lemma assumptions in place, all we have to show that  $G'.\text{po}$  and  $G'.\text{rf}; [\mathcal{U}]$  respect the order induced by  $\ell'$ .

The  $G'.\text{po}$  constraint is trivial. The only part that needs clarification is  $G'.\text{rf}; [\mathcal{U}]$ . Consider the cases:

- The  $G'.\text{rf}; [\mathcal{U}]$  edge is contained in the program order:  $G'.\text{rf}; [\mathcal{U}] \subseteq G'.\text{po}$ . This is trivial as our list respects the  $G'.\text{po}$  order.
- The  $G'.\text{rf}; [\mathcal{U}]$  edge starts in G.W (i.e., determined event):  $G'.\text{rf}; [\mathcal{U}] \subseteq [G.W]; G'.\text{rf}; [\mathcal{U}]$ . In this case the write event  $w$  from which the uncommitted read event  $\text{read-from}$  does not belong to  $\ell'$ , and thus is not a subject of the constraint. In other words, because the write event is contained within the graph from which the re-execution starts (i.e., it is a determined event), the read event reading from it can be added at any point during the re-execution.
- The  $G'.\text{rf}; [\mathcal{U}]$  edge is between events from different threads, and does not start in G.W. This means the events have to be ordered by  $G'.\text{tid} \downarrow \prec_{\text{tid}}$ , as dictated by the predicate  $\text{ThreadOrderedUEvents}(G', C, \prec_{\text{tid}})$ , making them immediately ordered by the  $\ell'$  list order.

□

**Corollary 2.** *Let  $G, G', C, \mathcal{U}, \Delta, \ell$  be defined similarly as in Lemma 2, and suppose that  $\Delta \subseteq G'.E|_t$  for some thread  $t$ . Then  $\text{ThreadOrderedUEvents}(G', C, \prec_{\text{tid}})$  holds.*

PROOF. It is sufficient to notice that a choice of  $\prec_{\text{tid}}$  ordering that defines the thread  $t$  as a maximal element and lets all other threads to be unordered trivially satisfies the predicate  $\text{ThreadOrderedUEvents}(G', C, \prec_{\text{tid}})$ . □

**Lemma 6.** *Let  $G, G', C, \mathcal{U}, \Delta$  be defined similarly as in Lemma 2. In particular,  $\text{WellFormed}(G, G', C)$  and  $\text{WellFormed}(G')$  hold. Moreover, suppose the predicate  $\text{ThreadOrderedUEvents}(G', C, \prec_{\text{tid}})$  holds. Additionally, assume the internal  $\text{rf}; [\mathcal{U}]$  respects the program order:  $G'.\text{rf}; [\mathcal{U}] \cap \equiv_{\text{tid}} \subseteq G'.\text{po}$ . Finally, assume that  $G'$  is  $\text{rf}$ -complete and  $\Delta$  is finite.*

*Then, the graph  $G'$  can be constructed from  $G$ :*

$$\langle G', C \rangle \vdash G \Rightarrow^* G'$$

PROOF. To prove this lemma, all we need to do is to present a list  $\ell$ , and apply the Lemma 1.

Let  $\ell$  be any enumeration of  $\Delta$ , that respects  $G'.\text{po}$  and  $G'.\text{tid} \downarrow \prec_{\text{tid}}$  — we can construct such a list because  $\text{ThreadOrderedUEvents}(G', C, \prec_{\text{tid}})$  holds. All we need to do is to show that  $G'.\text{po} \cup G'.\text{rf}; [\mathcal{U}]$  respects the order induced by  $\ell$ . This follows immediately from the lemma assumptions and the construction of  $\ell$ . □

**Corollary 3.** *A re-execution of a single thread is always feasible.*

*That is, given  $G, G', C, \mathcal{U}, \Delta$  defined similarly as in Lemma 6, such that  $\Delta \subseteq G'.E|_t$  for some thread  $t$ , and assuming internal  $\text{rf}; [\mathcal{U}]$  respects the program order, then:*

$$\langle G', C \rangle \vdash G \Rightarrow^* G'$$

PROOF. Follows directly from Lemma 6 and Corollary 2. □

## B Proofs of C20 consistency properties

**Definition 17.** Given a relation  $R \subseteq X \times X$ , and two sets  $\mathcal{A}, \mathcal{B} \subseteq X$ , we define several auxiliary relations (for the convenience of the proofs, we let  $\mathcal{A}, \mathcal{B}$  be arbitrary sets, but typically we use either singleton sets or empty sets):

- $InsertBefore(R, \mathcal{A}, \mathcal{B})$  – inserts  $\mathcal{B}$  right before  $\mathcal{A}$  in the relation  $R$ :

$$InsertBefore(R, \mathcal{A}, \mathcal{B}) \triangleq \mathcal{B} \times \mathcal{A} \cup \text{dom}(R; [\mathcal{A}]) \times \mathcal{B} \cup \mathcal{B} \times \text{codom}([\mathcal{A}]; R)$$

- $InsertAfter(R, \mathcal{A}, \mathcal{B})$  – inserts  $\mathcal{B}$  right after  $\mathcal{A}$  in the relation  $R$ :

$$InsertAfter(R, \mathcal{A}, \mathcal{B}) \triangleq \mathcal{A} \times \mathcal{B} \cup \text{dom}(R; [\mathcal{A}]) \times \mathcal{B} \cup \mathcal{B} \times \text{codom}([\mathcal{A}]; R)$$

- $Swap(R, \mathcal{A}, \mathcal{B})$  – swaps edges going between  $\mathcal{A}$  and  $\mathcal{B}$  in the relation  $R$ :

$$Swap(R, \mathcal{A}, \mathcal{B}) \triangleq R \setminus \mathcal{A} \times \mathcal{B} \cup \mathcal{B} \times \mathcal{A}$$

Additionally, let  $G$  be an execution graph, and let  $e \in G.E$  be its event. We give the following auxiliary definitions:

- $WriteOf(G, e)$  – is either an event  $e$  itself, if it is a write event, or it is a write event from which  $e$  reads-from, if it is a read event (for the convenience of the proofs, we actually define  $WriteOf$  as a set):

$$WriteOf(G, e) = \begin{cases} \{e\} & \text{if } e \in G.W \\ \{w\} & \text{if } e \in G.R \text{ and } \langle w, e \rangle \in G.rf \\ \emptyset & \text{otherwise} \end{cases}$$

**Proposition\*.** *The following statements are true:*

- (1)  $po; sw = rpo; sw$  and  $sw; po = sw; rpo$
- (2)  $hb = po \cup rhb$
- (3)  $hb|_{loc} = rhb|_{loc}$
- (4)  $hb \cap \neq_{tid} = rhb \cap \neq_{tid}$

PROOF.

- (1) **Proving**  $po; sw = rpo; sw$ .

By definition,  $sw$  starts with  $[\mathcal{E}^{REL}]$ , which means that we have  $po; [\mathcal{E}^{REL}]$  and this is an  $rpo$ -edge.

- (2) **Proving**  $sw; po = sw; rpo$ .

By definition,  $sw$  ends with  $[\mathcal{E}^{ACQ}]$ , which means that we have  $[\mathcal{E}^{ACQ}]; po$  and this is an  $rpo$ -edge.

- (3) **Proving**  $hb = po \cup rhb$ .

Inclusion  $po \cup rhb \subseteq hb$  is trivial. To prove the other inclusion, we can rewrite  $hb$  and  $rhb$  by definition, and then do a case analysis of the path in  $hb$ .

$$(po \cup sw)^+ \subseteq po \cup (po|_{loc} \cup rpo \cup sw)^+$$

We can use the following facts to simplify or replace the path:

- $po$  is transitive;
- any  $po$ -edge followed or preceded by  $sw$ -edge can be replaced by  $rpo$ -edge, as was shown above.

So if the path contains  $po$ -edges only, it is contained in  $po$  and if it contains at least one  $sw$ -edge, all the continuous  $po$ -paths can firstly be collapsed into single  $po$ -edges and then replaced by  $rpo$ -edges, which is contained in  $(po|_{loc} \cup rpo \cup sw)^+$ .

- (4) **Proving**  $hb|_{loc} = rhb|_{loc}$ .

Applying the previous property, we need to show that  $(po \cup rhb)|_{loc} \subseteq rhb|_{loc}$ . Hence, we need to show that  $po|_{loc} \subseteq rhb|_{loc}$ . By definition,  $rhb = (po|_{loc} \cup rpo \cup sw)^+$ , and by definition,  $rpo$  contains  $po|_{loc}$ , which finalizes the proof.

- (5) Applying the property (2) to the relation, we obtain the result.

□

**Lemma.** C20 coherence is equivalent to the following statement:

$$\text{rhh}; \text{eco}^? \text{ is irreflexive}$$

PROOF. Since  $\text{eco}^?$  connects events of the same location, then  $\text{rhh}$  is also restricted by the same location. Thus, applying Proposition 1 finalizes the proof. □

**Definition 18.** Memory consistency model  $\mathcal{M}$  is called *monotone* if for every execution graphs  $G'$  and  $G$ , an event mapping function  $m : G'.E \rightarrow G.E$  consistency of  $G'$  implies consistency of  $G$ :

$$\text{Consistent}(\mathcal{M}, G') \implies \text{Consistent}(\mathcal{M}, G)$$

provided that the following conditions are met:

- $m$  is injective
- $G.\text{tid} \circ m = G'.\text{tid}$
- $G.\text{lab} \circ m = G'.\text{lab}$
- $G.E \subseteq m \uparrow G'.E$
- $G.\text{po} \subseteq m \uparrow G'.\text{po}$
- $G.\text{rf} \subseteq m \uparrow G'.\text{rf}$
- $G.\text{mo} \subseteq m \uparrow G'.\text{mo}$
- $G.\text{rmw} \subseteq m \uparrow G'.\text{rmw}$
- $G.\text{rhh} \subseteq m \uparrow G'.\text{rhh}$

**Lemma 7.** C20 is monotone.

PROOF.

(Coherence)

We need to prove that  $G.\text{rhh}; G.\text{eco}^?$  is irreflexive. Since  $G.\text{rhh}$  is irreflexive by inclusion into the  $m \uparrow G.\text{rhh}$ , it is sufficient to prove that  $G.\text{rhh}; G.\text{eco}$  is irreflexive. Easy to see that  $G.\text{fr} \subseteq m \uparrow G'.\text{fr}$  and hence  $G.\text{eco} \subseteq m \uparrow G'.\text{eco}$ . Therefore,  $G.\text{rhh}; G.\text{eco} \subseteq m \uparrow (G'.\text{rhh}; G'.\text{eco})$ , which is irreflexive by the Coherence property of  $G'$ .

(Atomicity)

We need to prove that  $G.\text{rmw} \cap (G.\text{fr}; G.\text{mo}) \equiv \emptyset$ . As already obtained,  $G.\text{fr} \subseteq m \uparrow G'.\text{fr}$ , hence

$$G.\text{rmw} \cap (G.\text{fr}; G.\text{mo}) \subseteq m \uparrow (G'.\text{rmw} \cap G'.\text{fr}; G'.\text{mo}) \equiv \emptyset$$

□

**Definition 19.** Memory consistency model  $\mathcal{M}$  is called *maximal read extensible* if for every execution graphs  $G'$  and  $G$ , an event mapping function  $m : G'.E \rightarrow G.E$ , and a read event  $r \in G.E$  consistency of  $G'$  implies consistency of  $G$ :

$$\text{Consistent}(\mathcal{M}, G') \implies \text{Consistent}(\mathcal{M}, G)$$

provided that the following conditions are met (where  $R \triangleq \{r\}$ ):

- $m$  is injective
- $G.\text{tid} \circ m = G'.\text{tid}$
- $G.\text{lab} \circ m =_{|G'.E \setminus m \uparrow R} G'.\text{lab}$
- $G.E = m \uparrow G'.E \cup R$
- $\text{codom}([R]; G.\text{rpo}) = \emptyset$
- $G.\text{rpo}; [G.E \setminus R] \subseteq m \uparrow G'.\text{rpo}$
- $\text{codom}([R]; G.\text{po}|_{\text{loc}}) = \emptyset$

- $G.\text{po}|_{\text{loc}}; [G.E \setminus R] \subseteq m \uparrow G'.\text{po}|_{\text{loc}}$
- $G.\text{rf} = m \uparrow G'.\text{rf} \cup G.\text{srf}; [R]$
- $G.\text{mo} = m \uparrow G'.\text{mo}$
- $G.\text{rmw} \subseteq m \uparrow G'.\text{rmw}$

**Lemma 8.** *C20 is maximal read extensible.*

PROOF. (Coherence)

We need to prove that  $G.\text{hb}; G.\text{eco}^?$  is irreflexive. Let us first prove that  $G.\text{hb}$  is irreflexive. By Proposition 1, we know that  $G.\text{hb} = G.\text{po} \cup G.\text{rhb}$ . Since  $\text{po}$  is irreflexive, it is left to show that  $G.\text{rhb}$  is irreflexive. There are two possible cases: it can be either  $\text{rhb}; [R]$  cycle or not. If not, then it is irreflexive by the Coherence property of  $G'$ . If it is, then we can use the fact that  $\text{codom}([R]; G.\text{rhb}) = \emptyset$ . Let us prove it as well.

It can be rewritten in the following way:

$$\begin{aligned} & \text{codom}([R]; G.\text{rpo}); (G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw})^* \\ & \cup \text{codom}([R]; G.\text{sw}); (G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw})^* \\ & \cup \text{codom}([R]; G.\text{po}|_{\text{loc}}); (G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw})^* = \emptyset \end{aligned}$$

The first and thirds summand are empty, since  $\text{codom}([R]; G.\text{rpo}) = \emptyset$  and  $\text{codom}([R]; G.\text{po}|_{\text{loc}}) = \emptyset$ . And the second is empty, since  $\text{sw}$  starts with a write event or fence, and  $R$  is a read event.

So, since  $G.\text{hb}$  is irreflexive by construction, it is sufficient to prove that  $G.\text{hb}; G.\text{eco}$  is irreflexive. The latter is equivalent to  $G.\text{rhb}; G.\text{eco}$  being irreflexive.

We know that  $G'.\text{hb}; G'.\text{eco}$  is irreflexive. It is also equivalent to  $G'.\text{rhb}; G'.\text{eco}$  being irreflexive.

We also know that:

$$\begin{aligned} G.\text{fr} &= G.\text{rf}^{-1}; G.\text{mo} \subseteq m \uparrow G'.\text{fr} \cup [R]; G.\text{srf}^{-1}; G.\text{mo} \\ G.\text{eco} &= G.\text{rf} \cup G.\text{mo}; G.\text{rf}^? \cup G.\text{fr}; G.\text{rf}^? \\ &\subseteq m \uparrow G'.\text{eco} \\ &\cup G.\text{srf}; [R] \\ &\cup G.\text{mo}; G.\text{srf}; [R] \\ &\cup G.\text{fr}; G.\text{srf}; [R] \\ &\cup [R]; G.\text{srf}^{-1}; G.\text{mo}; G.\text{rf}^? \\ G.\text{rhb}; [G.E \setminus R] &\subseteq m \uparrow G'.\text{rhb} \\ G.\text{rhb}; G.\text{eco} &\subseteq m \uparrow (G'.\text{rhb}; G'.\text{eco}) \\ &\cup G.\text{rhb}; G.\text{srf}; [R] \\ &\cup G.\text{rhb}; G.\text{mo}; G.\text{srf}; [R] \\ &\cup G.\text{rhb}; G.\text{fr}; G.\text{srf}; [R] \\ &\cup G.\text{rhb}; [R]; G.\text{srf}^{-1}; G.\text{mo}; G.\text{rf}^? \end{aligned}$$

So it remains to show that the following relations are irreflexive:

- $G.\text{rhb}; G.\text{srf}; [R]$
- $G.\text{rhb}; G.\text{mo}; G.\text{srf}; [R]$
- $G.\text{rhb}; G.\text{fr}; G.\text{srf}; [R]$
- $G.\text{rhb}; [R]; G.\text{srf}^{-1}; G.\text{mo}; G.\text{rf}^?$

The first three irreflexivity proofs can be obtained from the fact that  $\text{codom}([R]; G.\text{rhh}) = \emptyset$ . For the last one, firstly, we can rotate the relation in the following way:  $G.\text{mo}; G.\text{rf}^2; G.\text{rhh}; [R]; G.\text{srf}^{-1}$ , since, we are aiming to proof irreflexivity. Then, we can rewrite it as

$$G.\text{mo}; [W]; G.\text{rf}^2; G.\text{rhh}; [R]; G.\text{srf}^{-1},$$

since  $\text{mo}$ -edge ends with write event. And now we can rewrite  $[W]; G.\text{rf}^2; G.\text{rhh}^2 \subseteq \text{vf}$  and obtain  $G.\text{mo}; G.\text{vf}; (G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw}); [R]; G.\text{srf}^{-1}$ . Since  $\text{codom}([R]; G.\text{rpo}) = \emptyset$  and  $\text{codom}([R]; G.\text{po}|_{\text{loc}}) = \emptyset$ , we only need to prove that  $G.\text{mo}; G.\text{vf}; G.\text{sw}; [R]; G.\text{srf}^{-1}$  is empty. That would be true following from  $G.\text{sw} \subseteq m \uparrow G'.\text{sw}$ . Let us show that.

By definition,

$$\text{sw} = [\mathcal{E}^{\text{REL}}]; ([F]; \text{po})^2; [W^{\text{RLX}}]; (\text{rf}; \text{rmw})^*; \text{rf}; [R^{\text{RLX}}]; (\text{po}; [F])^2; [\mathcal{E}^{\text{ACQ}}]$$

As  $\text{rmw}$ -edges are preserved by  $m$ , they can not start with  $R$ -event, meaning that the only possibility of where  $R$  can exist in this construction is  $[R^{\text{RLX}}]$  or in the last position. If there is no  $\text{po}$  at the end of the construction, then we obtain that  $R$  should be an acquire event, which is not possible. And if there is  $\text{po}$  in the end, then it can be replaced by  $\text{rpo}$ , leading to a contradiction with the fact that  $\text{codom}([R]; G.\text{rpo}) = \emptyset$ .

Now it is remaining to show that  $G.\text{rhh}; [G.E \setminus R] \subseteq m \uparrow G'.\text{rhh}$ . Let us show that by induction. Firstly, we can easily obtain that

$$G.\text{rhh} = (G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw}); [G.E \setminus R] \subseteq m \uparrow (G'.\text{po}|_{\text{loc}} \cup G'.\text{rpo} \cup G'.\text{sw})$$

from the property on codomain and  $\text{sw}$ . From that, we can easily prove

$$\begin{aligned} m \uparrow (G'.\text{po}|_{\text{loc}} \cup G'.\text{rpo} \cup G'.\text{sw})^+; (G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw}); [G.E \setminus R] \\ \subseteq m \uparrow (G'.\text{po}|_{\text{loc}} \cup G'.\text{rpo} \cup G'.\text{sw})^+ \end{aligned}$$

which will lead us to

$$((G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw}); [G.E \setminus R])^+ \subseteq m \uparrow (G'.\text{po}|_{\text{loc}} \cup G'.\text{rpo} \cup G'.\text{sw})^+$$

and the left part essentially equals to  $(G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw})^+; [G.E \setminus R]$ , since none of the edges from  $G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw}$  can not start in  $R$  and end in any other event, which finalizes the proof.

(Atomicity)

We need to prove that  $G.\text{rmw} \cap (G.\text{fr}; G.\text{mo}) \equiv \emptyset$ . Using  $G.\text{fr} \subseteq m \uparrow G'.\text{fr} \cup [R]; G.\text{srf}^{-1}; G.\text{mo}$ , we can rewrite the intersection as

$$m \uparrow G'.\text{rmw} \cap (m \uparrow (G'.\text{fr}; G'.\text{mo}) \cup [R]; G.\text{srf}^{-1}; G.\text{mo}; G.\text{mo}),$$

where we can remove  $[R]; G.\text{srf}^{-1}; G.\text{mo}; G.\text{mo}$ , since  $m \uparrow G'.\text{rmw}$  can not begin with new event  $R$ . The latter is empty by the Atomicity property of  $G'$ .

□

**Definition 20.** Memory consistency model  $\mathcal{M}$  is called *maximal write extensible* if for every execution graphs  $G'$  and  $G$ , an event mapping function  $m : G'.E \rightarrow G.E$ , and a write event  $w \in G.E$  consistency of  $G'$  implies consistency of  $G$ :

$$\text{Consistent}(\mathcal{M}, G') \implies \text{Consistent}(\mathcal{M}, G)$$

provided that the following conditions are met (where  $W \triangleq \{w\}$ ):

- $m$  is injective
- $G.\text{tid} \circ m = G'.\text{tid}$

- $G.\text{lab} \circ m =_{|G'.E \setminus m \downarrow W} G'.\text{lab}$
- $G.E = m \uparrow G'.E \cup W$
- $\text{codom}([W]; G.\text{rpo}) = \emptyset$
- $G.\text{rpo}; [G.E \setminus W] \subseteq m \uparrow G'.\text{rpo}$
- $\text{codom}([W]; G.\text{po}|_{\text{loc}}) = \emptyset$
- $G.\text{po}|_{\text{loc}}; [G.E \setminus W] \subseteq m \uparrow G'.\text{po}|_{\text{loc}}$
- $G.\text{rf} = m \uparrow G'.\text{rf}$
- $G.\text{mo} = m \uparrow G'.\text{mo} \cup (G.W_{\text{loc}(w)} \setminus W) \times W$
- $G.\text{rmw} \subseteq m \uparrow G'.\text{rmw}$

**Lemma 9.** *C20 is maximal write extensible.*

PROOF. (Coherence)

We need to prove that  $G.\text{hb}; G.\text{eco}^?$  is irreflexive. We will prove the irreflexivity of  $G.\text{hb}$  later, so now it is sufficient to prove that  $G.\text{hb}; G.\text{eco}$  is irreflexive. The latter is equivalent to  $G.\text{rhb}; G.\text{eco}$  being irreflexive.

We know that  $G'.\text{hb}; G'.\text{eco}$  is irreflexive. It is also equivalent to  $G'.\text{rhb}; G'.\text{eco}$  being irreflexive.

We also know that:

$$\begin{aligned}
 G.\text{fr} &= G.\text{rf}^{-1}; G.\text{mo} \\
 &= m \uparrow G'.\text{fr} \cup m \uparrow G'.\text{rf}^{-1}; ((G.W_{\text{loc}(w)} \setminus W) \times W) \\
 G.\text{eco} &= G.\text{rf} \cup G.\text{mo}; G.\text{rf}^? \cup G.\text{fr}; G.\text{rf}^? \\
 &= m \uparrow G'.\text{rf} \\
 &\quad \cup m \uparrow (G'.\text{mo}; G'.\text{rf}^?) \\
 &\quad \cup m \uparrow (G'.\text{fr}; G'.\text{rf}^?) \\
 &\quad \cup ((G.W_{\text{loc}(w)} \setminus W) \times W); (m \uparrow G'.\text{rf}^?) \\
 &\quad \cup (m \uparrow G'.\text{rf}^{-1}); ((G.W_{\text{loc}(w)} \setminus W) \times W); (m \uparrow G'.\text{rf}^?) \\
 G.\text{rhb}; [G.E \setminus W] &\subseteq m \uparrow G'.\text{rhb} \\
 G.\text{rhb}; G.\text{eco} &\subseteq m \uparrow (G'.\text{rhb}; G'.\text{eco}) \\
 &\quad \cup G.\text{rhb}; ((G.W_{\text{loc}(w)} \setminus W) \times W); G.\text{rf}^? \\
 &\quad \cup G.\text{rhb}; G.\text{rf}^{-1}; ((G.W_{\text{loc}(w)} \setminus W) \times W); G.\text{rf}^?
 \end{aligned}$$

Irreflexivity of the first summand follows from the irreflexivity of  $G'.\text{rhb}; G'.\text{eco}$ . Then, in the last two summands, we can reduce  $\text{rf}$ -edge in the end, since no new  $\text{rf}$ -edges were added and they can not start with  $W$ . Therefore, we can rewrite the last two summands in the following way:  $[W]; G.\text{rhb}; \dots$ , which is empty, since  $\text{codom}([W]; G.\text{rpo}) = \emptyset$  and  $G.\text{sw} \subseteq m \uparrow G'.\text{sw}$ , meaning that  $G.\text{rhb}$  can not begin with  $W$ .

Let us prove that  $G.\text{sw} \subseteq m \uparrow G'.\text{sw}$ . By definition,

$$\text{sw} = [\mathcal{E}^{\text{REL}}]; ([F]; \text{po})^?; [W^{\text{RLX}}]; (\text{rf}; \text{rmw})^*; \text{rf}; [R^{\text{RLX}}]; (\text{po}; [F])^?; [\mathcal{E}^{\text{ACQ}}]$$

We should show that any  $G.\text{sw}$  edge has  $m$ -preimage in  $G'$ . Since  $\text{rf}$  and  $\text{rmw}$ -edges are preserved by  $m$ , they can not start or end with  $W$ , meaning that all the events in the  $G.\text{sw}$ -construction have  $m$ -preimage in  $G'$ . Also, if there is a  $\text{po}$ -edge in the  $G.\text{sw}$ -construction, it can be replaced by  $\text{rpo}$ -edge, following from the definition of  $\text{rpo}$ . Hence, all the edges in the construction have

m-preimage in  $G'$  and the correspondent **sw**-preimage exists in  $G'$ . Moreover, in the following proof, we will need a weaker condition:  $G.\text{sw} \subseteq m \uparrow G'.\text{sw} \cup G.\text{sw}; [W]$ .

Now we can also prove irreflexivity of  $G.\text{hb}$ . By Proposition 1, we know that  $G.\text{hb} = G.\text{po} \cup G.\text{rhh}$ . Since  $\text{po}$  is irreflexive, it is left to show that  $G.\text{rhh}$  is irreflexive. There are two possible cases: it can be either  $\text{rhh}; [W]$  cycle or not. If not, then it is irreflexive by the Coherence property of  $G'$ . If it is, then we can use the fact that  $\text{codom}([W]; G.\text{rhh}) = \emptyset$ . Let us prove it as well.

It can be rewritten in the following way:

$$\begin{aligned} & \text{codom}([W]; G.\text{rpo}); ((G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw}))^* \cup \\ & \text{codom}([W]; G.\text{po}|_{\text{loc}}); ((G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw}))^* \cup \\ & \text{codom}([W]; G.\text{sw}); ((G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw}))^* = \emptyset \end{aligned}$$

The first two summands are empty from the codomain conditions. And the second is empty, since  $m \uparrow G'.\text{sw}$  can not start with  $W$  and  $\text{codom}([W]; G.\text{sw}) = \emptyset$ . The latter is easily obtained from the definition of **sw**.

Now it is remaining to show that  $G.\text{rhh}; [G.E \setminus W] \subseteq m \uparrow G'.\text{rhh}$ . Let us show that by induction. Firstly, we can easily obtain that

$$G.\text{rhh} = (G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw}); [G.E \setminus W] \subseteq m \uparrow (G'.\text{po}|_{\text{loc}} \cup G'.\text{rpo} \cup G'.\text{sw})$$

from the property on codomain and **sw**. From that, we can easily prove

$$\begin{aligned} m \uparrow (G'.\text{po}|_{\text{loc}} \cup G'.\text{rpo} \cup G'.\text{sw})^+; (G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw}); [G.E \setminus W] \\ \subseteq m \uparrow (G'.\text{po}|_{\text{loc}} \cup G'.\text{rpo} \cup G'.\text{sw})^+ \end{aligned}$$

which will lead us to

$$((G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw}); [G.E \setminus W])^+ \subseteq m \uparrow (G'.\text{po}|_{\text{loc}} \cup G'.\text{rpo} \cup G'.\text{sw})^+$$

and the left part essentially equals to  $(G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw})^+; [G.E \setminus W]$ , since none of the edges from  $G.\text{po}|_{\text{loc}} \cup G.\text{rpo} \cup G.\text{sw}$  can not start in  $W$  and end in any other event, which finalizes the proof.

(Atomicity)

We need to prove that  $G.\text{rmw} \cap (G.\text{fr}; G.\text{mo}) \equiv \emptyset$ . Using

$$\text{fr} \subseteq m \uparrow G'.\text{fr} \cup m \uparrow G'.\text{rf}^{-1}; ((G.W_{\text{loc}(w)} \setminus W) \times W),$$

we can rewrite the intersection as

$$\begin{aligned} m \uparrow G'.\text{rmw} \cap (m \uparrow (G'.\text{fr}; G'.\text{mo}) \cup (m \uparrow G'.\text{fr}); ((G.W_{\text{loc}(w)} \setminus W) \times W) \\ \cup (m \uparrow G'.\text{rf}^{-1}); ((G.W_{\text{loc}(w)} \setminus W) \times W); (m \uparrow G'.\text{mo}) \\ \cup (m \uparrow G'.\text{rf}^{-1}); ((G.W_{\text{loc}(w)} \setminus W) \times W); ((G.W_{\text{loc}(w)} \setminus W) \times W)) \end{aligned}$$

The last three summands are empty as  $m \uparrow G'.\text{rmw}$  can not end with  $W$  or  $(m \uparrow G'.\text{mo})$  can not start with  $W$ . The remaining intersection is empty by the Atomicity property of  $G'$ .  $\square$

**Definition 21.** Memory consistency model  $\mathcal{M}$  is called *overwrite extensible* if for every execution graphs  $G'$  and  $G$ , an event mapping function  $m : G'.E \rightarrow G.E$ , a write event  $w' \in G'$ , and a write event  $w \in G.E$ , consistency of  $G'$  implies consistency of  $G$ :

$$\text{Consistent}(\mathcal{M}, G') \implies \text{Consistent}(\mathcal{M}, G)$$

provided that the following conditions are met (where  $W' \triangleq \{w'\}$  and  $W \triangleq \{w\}$ ):

- $m$  is injective

- $G.tid \circ m = G'.tid$
- $G.lab \circ m = \downarrow_{G'.E \setminus m \downarrow W} G'.lab$
- $G.E = m \uparrow G'.E \cup W$
- $G.po = m \uparrow G'.po \cup \text{InsertBefore}(m \uparrow G'.po, m \uparrow W', w)$
- $G.rf = m \uparrow G'.rf$
- $G.mo = m \uparrow G'.mo \cup \text{InsertBefore}(m \uparrow G'.mo, m \uparrow W', w)$
- $G.rmw = m \uparrow G'.rmw$

**Lemma 10.** *C20 is overwrite extensible.*

PROOF. (Coherence)

We need to prove that  $G.\text{hb}; G.\text{eco}^?$  is irreflexive. We will prove that  $G.\text{hb}$  is irreflexive later, so now it is sufficient to prove that  $G.\text{hb}; G.\text{eco}$  is irreflexive.

We know that

$$\begin{aligned}
 G.fr &= G.rf^{-1}; G.mo \\
 &\subseteq m \uparrow G'.fr \cup G.rf^{-1}; \text{InsertBefore}(m \uparrow G'.mo, m \uparrow W', w) \\
 G.eco &= G.rf \cup G.mo; G.rf^? \cup G.fr; G.rf^? \\
 &\subseteq m \uparrow G'.rf \\
 &\cup m \uparrow (G'.mo; G'.rf^?) \\
 &\cup m \uparrow (G'.fr; G'.rf^?) \\
 &\cup \text{InsertBefore}(m \uparrow G'.mo, m \uparrow W', w); G.rf^? \\
 &\cup G.rf^{-1}; \text{InsertBefore}(m \uparrow G'.mo, m \uparrow W', w); G.rf^?
 \end{aligned}$$

Therefore, we have

$$\begin{aligned}
 G.hb; G.eco &\subseteq G.hb; m \uparrow G'.eco \\
 &\cup G.hb; \text{InsertBefore}(m \uparrow G'.mo, m \uparrow W', w); G.rf^? \\
 &\cup G.hb; G.rf^{-1}; \text{InsertBefore}(m \uparrow G'.mo, m \uparrow W', w); G.rf^?
 \end{aligned}$$

To operate with  $\text{hb}$ -edges, we should notice that  $G.hb = m \uparrow G'.hb \cup [w]; G.hb \cup G.hb; [w]$ . For this, let us first prove that  $G.sw = m \uparrow G'.sw$ . So, we should show that all the  $G'.sw$ -edges are mapped to  $G.sw$ -edges and no new  $G.sw$ -edges are added. By definition,

$$sw = [\mathcal{E}^{\text{REL}}]; ([F]; po)^?; [W^{\text{RLX}}]; (rf; rmw)^*; rf; [R^{\text{RLX}}]; (po; [F])^?; [\mathcal{E}^{\text{ACQ}}]$$

Hence, if we have an  $\text{sw}$ -edge, it consists of  $\text{po}$ -edges,  $\text{rf}$ -edges, and  $\text{rmw}$ -edges. It is easy to see, that if there was an  $G'.sw$ -edge, then it would remain an  $G.sw$ -edge as all of its parts are mapped into the corresponding classes of edges. Now, let's consider the reverse direction.  $\text{rf}$  and  $\text{rmw}$ -edges are preserved by  $m$ , and  $G.po$  can appear if it is an image of  $G'.po$  or if it is an edge between  $w$  and some other event  $a$ . The first case is fine and the second case is impossible to appear in  $\text{sw}$ , since that  $G.po$ -edge can be only in the first position of the  $\text{sw}$ -definition, and the following  $\text{rf}$ -edge can not start with a new event.

Now, let us proceed to  $G.hb = m \uparrow G'.hb \cup [w]; G.hb \cup G.hb; [w]$ . By definition,  $G.hb = (G.po \cup G.sw)^+$ , and in that path  $G.sw$ -edges connect only events from the target graph, and sequences of continuous  $G.po$ -edges can be merged into single  $G.po$ -edges by transitivity property. Therefore, all the events, in the  $(G.po \cup G.sw)^+$ -path, except for the first and the last ones (followed or preceded by a new  $\text{po}$ -edge respectively), are events from the target graph. Moreover, if there is

an edge of the form  $[w]; G.\text{hb}$  or  $G.\text{hb}; [w]$ , then in target graph there was a correspondent edge  $[w']; G'.\text{hb}$  or  $G'.\text{hb}; [w']$ .

After this, we can return to the proof of irreflexivity of  $G.\text{hb}; G.\text{eco}$ . Let us consider the first component of the summands:  $G.\text{hb}; m \uparrow G'.\text{eco}$ . We can rewrite it as

$$m \uparrow (G'.\text{hb}; G'.\text{eco}) \cup [w]; G.\text{hb}; m \uparrow G'.\text{eco} \cup G.\text{hb}; [w]; m \uparrow G'.\text{eco}.$$

The first part is irreflexive by the Coherence property of  $G'$ , and in the latter two, we can see that in the target graph there was an edge  $[w']; G'.\text{hb}$  or  $G'.\text{hb}; [w']$ , which contradicts the irreflexivity of  $G'.\text{hb}; G'.\text{eco}$ .

Now let's consider the second component of the summands:  $G.\text{hb}; \text{InsertBefore}(m \uparrow G'.\text{mo}, m \uparrow W', w); G'.\text{rf}^2$ . If the  $\text{rf}$ -edge doesn't exist, we come to a simple contradiction, and if it exists, then we have a cycle of the form  $[w]; G.\text{mo}; [m(w')]; G.\text{rf}; [m(r)]; G.\text{hb}$ , which means, that there was a  $G'.\text{hb}$ -edge between  $w'$  and  $r$ , which contradicts the irreflexivity of  $G'.\text{hb}; G'.\text{eco}$ .

The last component of the summands is  $G.\text{hb}; G'.\text{rf}^{-1}; \text{InsertBefore}(m \uparrow G'.\text{mo}, m \uparrow W', w); G'.\text{rf}^2$ . This case is impossible as  $G.\text{rf}$ -edges can not start with  $w$ , which finally proves the irreflexivity of  $G.\text{hb}; G.\text{eco}$ .

Let us now prove the irreflexivity of  $G.\text{hb}$ . By definition,  $\text{hb} = (\text{po} \cup \text{sw})^+$ , so essentially we have a path of po-edges and  $\text{sw}$ -edges. The po-edges can be merged into single po-edge by transitivity property, and  $\text{sw}$ -edges can not start with new event. Hence, if there are  $\text{sw}$ -edges in the path, then there are no new events inside of it, then a new event can be only in the beginning and the end of the path (since the end is the beginning in terms of irreflexivity). And if there are no  $\text{sw}$ -edges, then the path is a sequence of po-edges, which can be merged into a single po-edge. Now, if there is a new event  $w$  at the beginning of the path, then it is connected with something only via po-edges, hence there is respective  $\text{hb}$ -construction in the target graph with  $w$  replaced by  $w'$ , which contradicts the irreflexivity of  $G'.\text{hb}$ . And if there is  $m(e)$  with  $e \in G'.E$  at the end of the path, then there is the same  $\text{hb}$ -construction in the target graph, which contradicts the irreflexivity of  $G'.\text{hb}$ .

(Atomicity)

We need to prove that  $G.\text{rmw} \cap (G.\text{fr}; G.\text{mo}) \equiv \emptyset$ . Using

$$\text{fr} \subseteq m \uparrow G'.\text{fr} \cup G.\text{rf}^{-1}; \text{InsertBefore}(m \uparrow G'.\text{mo}, m \uparrow W', w),$$

we can rewrite the intersection as

$$\begin{aligned} & m \uparrow G'.\text{rmw} \cap (m \uparrow (G'.\text{fr}; G'.\text{mo})) \\ & \quad \cup m \uparrow G'.\text{fr}; \text{InsertBefore}(m \uparrow G'.\text{mo}, m \uparrow W', w) \\ & \quad \cup G.\text{rf}^{-1}; \text{InsertBefore}(m \uparrow G'.\text{mo}, m \uparrow W', w); m \uparrow G'.\text{mo} \\ & \quad \cup G.\text{rf}^{-1}; \text{InsertBefore}(m \uparrow G'.\text{mo}, m \uparrow W', w); \text{InsertBefore}(m \uparrow G'.\text{mo}, m \uparrow W', w) \end{aligned}$$

The second and the fourth summands are empty as  $G.\text{rf}$ -edges can not start with  $w$  and the third one as well, since  $\text{fr}$ -edge can not connect two writes. The remaining intersection is empty by the Atomicity property of  $G'$ .  $\square$

**Definition 22.** Memory consistency model  $\mathcal{M}$  is called *same-read extensible* if for every execution graphs  $G'$  and  $G$ , an event mapping function  $m : G'.E \rightarrow G.E$ , an event  $e' \in G'$ , and a read event  $r \in G.E$ , consistency of  $G'$  implies consistency of  $G$ :

$$\text{Consistent}(\mathcal{M}, G') \implies \text{Consistent}(\mathcal{M}, G)$$

provided that the following conditions are met (where  $R \triangleq \{r\}$ ):

- $m$  is injective
- $G.tid \circ m = G'.tid$
- $G.lab \circ m = \downarrow_{G'.E \setminus \{m\}R} G'.lab$
- $G.E = m \uparrow G'.E \cup R$
- $G.po = m \uparrow G'.po \cup InsertAfter(m \uparrow G.po, \{m(e')\}, R)$
- $G.rf = m \uparrow G'.rf \cup m \uparrow WriteOf(G', e') \times R$
- $G.mo = m \uparrow G'.mo$
- $G.rmw = m \uparrow G'.rmw$

**Lemma 11.** C20 is same-read extensible.

PROOF. (Consistency)

We need to prove that  $G.hb; G.eco^?$  is irreflexive. We will prove that  $G.hb$  is irreflexive later, so now it is sufficient to prove that  $G.hb; G.eco$  is irreflexive.

We know that

$$\begin{aligned}
 G.fr &= G.rf^{-1}; G.mo \\
 &\subseteq m \uparrow (G'.rf^{-1}; G'.mo) \cup R \times m \uparrow WriteOf(G', e'); G.mo \\
 G.eco &= G.rf \cup G.mo; G.rf^? \cup G.fr; G.rf^? \\
 &\subseteq m \uparrow G'.rf \\
 &\cup m \uparrow (G'.mo; G'.rf^?) \\
 &\cup m \uparrow (G'.fr; G'.rf^?) \\
 &\cup m \uparrow WriteOf(G', e') \times R \\
 &\cup G.mo; (m \uparrow WriteOf(G', e') \times R)^? \\
 &\cup m \uparrow G'.fr; (m \uparrow WriteOf(G', e') \times R)^? \\
 &\cup R \times m \uparrow WriteOf(G', e'); G.mo; G.rf^? \\
 &\cup R \times m \uparrow WriteOf(G', e'); G.mo; (m \uparrow WriteOf(G', e') \times R)^?
 \end{aligned}$$

Therefore, we have

$$\begin{aligned}
 G.hb; G.eco &\subseteq G.hb; m \uparrow G'.eco \\
 &\cup G.hb; m \uparrow WriteOf(G', e') \times R \\
 &\cup G.hb; G.mo; (m \uparrow WriteOf(G', e') \times R)^? \\
 &\cup G.hb; m \uparrow G'.fr; (m \uparrow WriteOf(G', e') \times R)^? \\
 &\cup G.hb; R \times m \uparrow WriteOf(G', e'); G.mo; G.rf^? \\
 &\cup G.hb; R \times m \uparrow WriteOf(G', e'); G.mo; (m \uparrow WriteOf(G', e') \times R)^?
 \end{aligned}$$

Let us first show that  $G.sw = m \uparrow G'.sw \cup G.sw; [r]$ . We should show that all the  $G'.sw$  edges are mapped to  $G.sw$ -edges and no new  $G.sw$ -edges are added. By definition,

$$sw = [\mathcal{E}^{REL}]; ([F]; po)^?; [W^{RLX}]; (rf; rmw)^*; rf; [R^{RLX}]; (po; [F])^?; [\mathcal{E}^{ACQ}]$$

Hence, if we have an  $sw$ -edge, it consists of  $po$ -edges,  $rf$ -edges, and  $rmw$ -edges. It is easy to see, that if there was an  $G'.sw$ -edge, then it would remain an  $G.sw$ -edge as all of its parts are mapped into the corresponding classes of edges. Now, let's consider the reverse direction. We have some path of  $sw$ -form between  $m(a)$  and  $m(b)$  in the source graph. If doesn't contain  $r$ , then it is mapped to the correspondent path in the target graph. If it contains  $r$ , we can consider all the possibilities

of where it can appear. It can not be a part of **rmw**-edge, since **rmw**-edges are preserved under  $m$ . Hence, the only possibility of  $r$  is to appear as  $[R^{RLX}]$  in definition of **sw**. So, there are two possibilities:  $r$  can be equal to  $m(b)$  or be between **rf** and **po**-edges. In the first case, we obtain  $G.sw; [r]$  and moreover, in the target graph there exists a correspondent **sw**-edge, starting from  $a$  and ending in  $e'$  (as we the rest of **sw**-elements are preserved and for the last  $G.rf$ -edge there is a correspondent  $G'.rf$ -edge ending in  $e'$ ). In the second case, we can see that the respective preceding and following **rf** and **po**-edges exist in the target graph for  $e'$ , hence, the correspondent **sw**-edge in the target graph exists as well.

Now, let us proceed to  $G.hb = m \uparrow G'.hb \cup [r]; G.hb \cup G.hb; [r]$ . By definition,  $G.hb = (G.po \cup G.sw)^+$ , and sequences of continuous  $G.po$ -edges can be merged into single  $G.po$ -edges by transitivity property. Therefore, we have three cases. First, the first or the last event is  $r$  – this case is fine, and additionally, if there is an edge of the form  $[r]; G.hb$  or  $G.hb; [r]$ , then in target graph there was a correspondent edge  $[e']; G'.hb$  or  $G'.hb; [e']$ . Second,  $r$  is in the middle of the path and the beginning and the end of the path are events from the target graph ( $c$  and  $d$ ). Hence, if we have a part of the form  $[m(a)]; G.sw; [r]; G.po; [m(b)]$ , then in the target graph there was a correspondent part of the form  $[a]; G'.sw; [e']; G'.po; [b]$ , which means that between the  $c$  and  $d$  there already was an  $G'.hb$ -edge (the rest of the edges between target events exist as well as  $m$ -preimages of correspondent edges). Lastly, if there is no  $r$  in the path, then all the events are from the target graph, the same path existed in the target path and the proof is finished.

After this, we can return to the proof of irreflexivity of  $G.hb; G.eco$ . Let us consider the first component of the summands:  $G.hb; m \uparrow G'.eco$ . We can rewrite it as

$$m \uparrow (G'.hb; G'.eco) \cup [r]; G.hb; m \uparrow G'.eco \cup G.hb; [r]; m \uparrow G'.eco.$$

The first part is irreflexive by the Coherence property of  $G'$ , and in the latter two, we can see that in the target graph there was an edge  $[e']; G'.hb$  or  $G'.hb; [e']$ , which contradicts the irreflexivity of  $G'.hb; G'.eco$ .

Now let's consider the rest of the summands.

- $G.hb; m \uparrow WriteOf(G', e') \times R$  is empty, such **hb**; **po** cycle is impossible.
- $G.hb; G.mo; (m \uparrow WriteOf(G', e') \times R)^?$ . If the latter edge doesn't exist, we come to a simple contradiction, and if it exists,  $e'$  is a write event, and since there is a **hb**-edge after  $r$ , then there is the same edge, starting from  $e'$ , which contradicts the irreflexivity of  $G'.hb; G'.eco$ .
- $G.hb; m \uparrow G'.fr; (m \uparrow WriteOf(G', e') \times R)^?$ . If the latter edge doesn't exist, then we have a subcase of the very first summand. And if it exists, then  $e'$  is a write event, and there is a **hb**-edge coming from  $e'$  (let's say to  $m(a)$ ), correspondent to the **hb**-edge coming from  $r$  into  $a$ , which leads contradiction with the irreflexivity of  $G'.hb; G'.eco$ .
- $G.hb; R \times m \uparrow WriteOf(G', e'); G.mo; G.rf^?$ . If the latter edge doesn't exist, then  $e'$  is a write event, there is a **hb**-edge incoming to  $e'$ , correspondent to the **hb**-edge incoming to  $r$ , which leads to a contradiction with the irreflexivity of  $G'.hb; G'.eco$  within the cycle of **hb**; **mo**. If the **rf**-edge exists, then from one side, **rf**-edge should end with the read event, and from the other side, the **mo**-edge after that should start with the write event, which is impossible.
- $G.hb; R \times m \uparrow WriteOf(G', e'); G.mo; (m \uparrow WriteOf(G', e') \times R)^?$ . If the latter edge doesn't exist, then we get a subcase of the fourth bullet. If it exists, then we have a **mo**-edge between  $WriteOf(G', e')$  and  $WriteOf(G', e')$ , which is impossible.

Therefore, we have shown that  $G.hb; G.eco$  is irreflexive.

Let us now prove the irreflexivity of  $G.hb$ . There are two cases: a cycle of the form  $G.hb; [r]$  or  $G.hb; [m(e)]$ , where  $e \in G'.E$ . In the second case, we can see that there is a correspondent  $G'.hb$ -edge in the target graph, which contradicts the irreflexivity of  $G'.hb$ . In the first case, let us

recall the definition of  $\text{hb} : \text{hb} = (\text{po} \cup \text{sw})^+$ , which is essentially a path of po-edges and  $\text{sw}$ -edges. The po-edges can be merged into a single po-edge by transitivity property. Now, we can substitute all the possible  $r$ -entries in the path by  $m(e')$ -entries, which means, that there was a correspondent  $G'.\text{hb}$ -edge in the target graph, which contradicts the irreflexivity of  $G'.\text{hb}$ . The only thing we have to ensure is that there are no  $[m(e')]; G.\text{po}; [r]$ -edges in this path, but this is impossible, since the following  $\text{sw}$ -edge can not start with  $r$ .

(Atomicity)

We need to prove that  $G.\text{rmw} \cap (G.\text{fr}; G.\text{mo}) \equiv \emptyset$ . Using

$$\text{fr} \subseteq m \uparrow (G'.\text{rf}^{-1}; G'.\text{mo}) \cup R \times m \uparrow \text{WriteOf}(G', e'); G.\text{mo},$$

we can rewrite the intersection as

$$m \uparrow G'.\text{rmw} \cap (m \uparrow (G'.\text{fr}; G'.\text{mo}) \cup R \times m \uparrow \text{WriteOf}(G', e'); G.\text{mo}; G.\text{mo})$$

The second summand is empty as  $G.\text{rmw}$ -edges can not start with  $r$ . The remaining intersection is empty by the Atomicity property of  $G'$ .  $\square$

## C Proof of Data Race Freedom Guarantees

In this section, we present a detailed proof of Lemma 4 — a key lemma used to prove the DRF guarantees in Theorem 1 (see §3.4 for the proof of the theorem itself). Below we repeat the statement of the lemma and proceed with its proof.

**Lemma.** *Let  $\mathcal{M}$  be a write-read coherent memory model, and  $P$  be a program, such that all of its  $\text{porf}$  acyclic  $\mathcal{M}$ -consistent execution graphs are relax (RLX) race-free. Suppose additionally that  $G$  is a  $\text{porf}$  acyclic  $\mathcal{M}$  consistent graph of this program. Then every graph  $G'$ , such that  $G \rightarrow G'$ , is also  $\text{porf}$  acyclic.*

**PROOF.** The statement is obviously true for the case of (Execute), as it only adds a single event that has no outgoing  $\text{porf}$  edges, and thus cannot form a new cycle.

The case of (Re-Execute) is more sophisticated. We need to consider a *re-execution frontier*  $\mathcal{F}$  that is a set of events from  $G'$  immediately succeeding determined events  $\mathcal{D}$  in program order. Without loss of generality, we can assume that the set  $\mathcal{F}$  consists of uncommitted reads, which read-from a different write event compared to  $G$ . If some event in the frontier does not satisfy these constraints, then it can be safely added to the set  $\mathcal{D}$  since it does not have to be re-executed.

Moreover, we can assume all reads in the frontier  $\mathcal{F}$  are relaxed. Otherwise, an acquire read would induce an  $\text{rpo}$  edge, which is forbidden by the (Re-Execute) rule.

From all the relaxed read events in the frontier  $\mathcal{F}$  we can pick one that is going to be re-executed first. Thus, during re-execution, it has to read from some write event lying in  $\mathcal{D}$ , and thus also belonging to  $G$ . So let  $r$  be the chosen read event,  $w_1$  be a write event it reads-from in  $G$ , and  $w_2$  be a write event it reads-from in  $G'$  (all three belong to  $G$ ).

In case if either  $w_1$  or  $w_2$  is in race with  $r$  we have a contradiction with the assumption that  $\text{porf}$  acyclic graphs of  $P$  are relax race-free. So let's consider the case when both  $w_1$  and  $w_2$  happen-before  $r$ .

We have that  $\langle w_1, r \rangle \in G.\text{hb}$  and  $\langle w_2, r \rangle \in G.\text{hb}$ . Note that it also implies  $\langle w_1, r \rangle \in G'.\text{hb}$  and  $\langle w_2, r \rangle \in G'.\text{hb}$ , because all three events belong to a common prefix of both graphs consisting of  $\mathcal{D}$  events.

Because  $G.\text{mo}$  is total it has to order  $w_1$  or  $w_2$  in one way or another.

Suppose the  $G.\text{mo}$  edge goes from  $w_1$  to  $w_2$ . Now we have a cycle  $r \xrightarrow{\text{fr}} w_2$  and  $w_2 \xrightarrow{\text{hb}} r$  in the graph  $G$ , which contradicts to write-read coherence implied by  $\mathcal{M}$ -consistency of  $G$ .

Symmetrically, let the  $G.\text{mo}$  edge go from  $w_1$  to  $w_2$ . Then we have a cycle  $r \xrightarrow{\text{fr}} w_1$  and  $w_1 \xrightarrow{\text{hb}} r$  in the graph  $G'$ , which contradicts to write-read coherence implied by  $\mathcal{M}$ -consistency of  $G'$ .  $\square$

## D Soundness of Compilation Mappings

We re-state the definition of the IMM model given in [Podkopaev et al. 2019].

**Definition 23.** We define *internal* and *external* versions of the reads-from and modification order:

$$\begin{aligned} \text{rfi} &\triangleq \text{rf} \cap =_{\text{tid}} & \text{moi} &\triangleq \text{mo} \cap =_{\text{tid}} \\ \text{rfe} &\triangleq \text{rf} \setminus =_{\text{tid}} & \text{moe} &\triangleq \text{mo} \setminus =_{\text{tid}} \end{aligned}$$

**Definition 24.** IMM model augments the execution graphs with additional *syntactic dependency* relations, that model the dependencies between instructions of a program on the level of events. In IMM, the execution graph is supplemented with the following relations: **data**—*data dependency*, **ctrl**—*control dependency*, **addr**—*address dependency*, and **casdep**—*compare-and-set dependency*.

The combined *dependency* relation **deps** is defined as follows:

$$\text{deps} \triangleq \text{data} \cup \text{ctrl} \cup \text{addr} ; \text{po}^? \cup \text{casdep}.$$

**Definition 25.** IMM introduces a number of derived relations given below.

- **ppo** is *preserved program order*, a subset of program order which includes ordering constraints due to syntactic dependencies:

$$\text{ppo} \triangleq [\text{R}] ; (\text{deps} \cup \text{rfi})^+ ; [\text{W}]$$

- **bob** is *barrier-order-before* relation, a subset of program order which includes ordering constraints due to memory fence placement:

$$\text{bob} \triangleq \text{po} ; [\text{W}^{\text{REL}}] \cup [\text{R}^{\text{ACQ}}] ; \text{po} \cup \text{po} ; [\text{F}] \cup [\text{F}] ; \text{po} \cup [\text{W}^{\text{REL}}] ; \text{po}_{\text{loc}} ; [\text{W}]$$

- **detour** associates a write event with a subsequent read event reading externally from the same memory location:

$$\text{detour} \triangleq (\text{moe} ; \text{rfe}) \cap \text{po}$$

- **ar** is the *acyclic relation*, a global causality relation on all the events in the IMM graph:

$$\text{ppo} \cup \text{bob} \cup \text{detour} \cup \text{rfe}$$

**Definition 26** (IMM consistency).

- $\text{R} \subseteq \text{codom}(\text{rf})$  (rf-COMPLETENESS)
- $\text{hb}; \text{eco}^?$  is irreflexive. (COHERENCE)
- $\text{rmw} \cap (\text{fr}; \text{mo})$  is empty (ATOMICITY)
- **ar** is an acyclic relation. (NO-THIN-AIR)

**Lemma 12.** Every IMM consistent graph is C20 consistent.

PROOF. Trivial, since C20 is weaker than IMM.  $\square$

Next, we re-state the compilation correctness theorem 2 from §3.5 and provide its proof.

**Theorem.** Let  $P$  be a program, and  $G$  be its IMM consistent execution graph. Then  $G$  is also an XC20 consistent execution graph.

PROOF. Note that by Lemma 12,  $G$  is C20 consistent.

Let  $[r_1, \dots, r_n]$  be a sequence of all the read events  $G.R$  of the given graph, ordered in accordance with the  $\text{ar}$  relation, that is  $\langle r_i, r_j \rangle \in \text{ar} \implies i < j$ .

We define a sequence of execution graphs  $[G_0, G_1, \dots, G_n, G_{n+1}]$ , where  $G_0 \triangleq G_{\text{init}}$ ,  $G_{n+1} \triangleq G$ , and for any other  $i$  graph  $G_i$  is defined as follows:

- $G_i.E = G.E \setminus \text{codom}([r_i]; (\text{ctrl} \cup \text{addr}; \text{po}^? \cup \text{casdep} \cup \text{bob}); \text{porf}^?)$
- $G_i.\text{tid} = G.\text{tid}|_{G_i.E}$
- $G_i.\text{lab} = G.\text{lab}|_{G_i.E}$
- $G_i.\text{po} = G.\text{po}|_{G_i.E}$
- $G_i.\text{rf} = G.\text{rf}|_{\{r_1, \dots, r_{i-1}\}} \cup G_{i+1}.\text{srf}; [\{r_i\}] \cup G_{i+1}.\text{rf}|_{\{r_{i+1}, \dots, r_n\}}$
- $G_i.\text{mo} = G.\text{mo}|_{G_i.E}$

To show that each graph  $G_i$  is IMM consistent, we use the following facts:

- $G_i$  is a subgraph of IMM consistent graph  $G$ , where some subset of read events was redirected to read-from stable write using  $\text{srf}$  relation;
- $\text{ar} \cup \text{srf}$  is an acyclic relation.

Therefore, for each  $i$  we have  $\text{Consistent}(G_i, \text{IMM})$ , and by Lemma 12 we also derive  $\text{Consistent}(G_i, \text{C20})$ .

We prove that for any  $i = 1 \dots n$  it is true that  $G_i \xrightarrow[\text{re-exec}]{C_i} G_{i+1}$  holds. To apply the re-execution rule, we set:

- $C_i \triangleq G_{i+1}.E \setminus \text{codom}([\{r_i\}]; G.\text{ar}^?)$
- $\mathcal{D}_i \triangleq G_i.E \setminus \text{codom}([\{r_i\}]; G_i.\text{po}^?)$
- $f_i \triangleq \text{id}$

The following properties follow immediately from these definitions:

- $C_i \subseteq G_{i+1}.E$
- $\mathcal{D}_i \subseteq \text{id} \upharpoonright C_i = C_i$
- $\text{dom}(G.\text{po}; [\mathcal{D}_i]) \subseteq \mathcal{D}_i$
- $\text{WellFormed}(G_i|_{\mathcal{D}_i}, G_{i+1}, C_i)$

$\text{ThreadOrderedUEvents}(G_{i+1}, C_i, \leq_{\text{tid}_i})$  holds trivially, since we re-execute single thread.

The  $\text{CommitEmbedded}(G_i, G_{i+1}, C_i, f_i)$  holds because  $C_i$  includes all the events, except those causally depending on  $r_i$  via  $\text{ar}$  relation. By definition of  $\text{ar}$  (as it includes syntactic dependency relation  $\text{deps}$  and external reads-from  $\text{rfe}$ ), changing the reads-from for  $r_i$  can only affect the events in its  $\text{ar}$  suffix — which are uncommitted. As such, all the committed events are going to be preserved during re-execution.

Moreover, it can be shown that none of the events in the threads outside re-executed thread causally depend via  $\text{ar}$  relation on  $r_i$ . Indeed, any  $\text{ar}$  path from  $r_i$  to some external event should start with  $\text{ppo}; \text{rfe}$ . Therefore, due to  $\text{rfe}$  edge, it would necessarily involve a read event  $r_j$ . That is,  $\langle r_i, r_j \rangle \in \text{ppo}; \text{rfe} \subseteq \text{ar}$ , and thus  $i < j$  by construction of the ordered list of reads  $[r_1, \dots, r_n]$ . As such, the read  $r_j$  had to be already redirected to read from stable write, and thus it cannot read externally via  $\text{rfe}$  — we get a contradiction.

Therefore, the re-execution is possible, and  $\langle G_{i+1}, C_i \rangle \vdash G_i|_{\mathcal{D}_i} \Rightarrow^* G_{i+1}$  holds.

Notice that in the graph  $G_0$  all reads are reading from stable writes (i.e., via  $\text{srf}$  relation), and thus this graph is  $\text{porf}$  acyclic. As such, it can be constructed using multiple execution steps:  $G_{\text{init}} \xrightarrow[\text{exec}]{*} G_1$ .

In conclusion, we have  $G_0 \rightarrow^* G_1 \dots \rightarrow^* G_n \rightarrow^* G_{n+1}$ , implying that  $G$  is XC20 consistent.

□

## E Soundness of Program Transformations

### E.1 Elimination

We prove the soundness of the elimination transformations on the level of the execution graphs by eliminating one of the two adjacent events.

**Definition 27.** We define a relation  $\mathcal{M}(G_s, G_t, m, a_t)$  asserting that the target graph  $G_t$  is obtained as a result of applying elimination transformation to the source graph  $G_s$ , where  $m : G_t.E \rightarrow G_s.E$  is an event mapping function,  $a_t$  is the eliminated event in  $G_t$ :

- $m$  is injective
- $G_s.E = m \uparrow G_t.E \cup \{a_s\}$
- $G_s.tid \circ m = G_t.tid$
- $G_s.lab \circ m = G_t.lab$
- $G_s.po = m \uparrow G_t.po \cup \mathcal{PO}$
- $G_s.rf = m \uparrow G_t.rf \cup \text{WriteOf}(G_t, a_t) \times (\{b_s\} \cap G_s.R)$
- $G_s.mo = m \uparrow G_t.mo \cup \text{InsertBefore}(m \uparrow G_t.mo, \{a_s\}, \{b_s\} \cap G_s.W)$
- $G_s.rmw = m \uparrow G_t.rmw$

where:

$$\mathcal{PO} \triangleq \begin{cases} \text{InsertBefore}(m \uparrow G_t.po, \{b_s\}, \{a_s\}) & \text{for Store-Store elimination} \\ \text{InsertAfter}(m \uparrow G_t.po, \{a_s\}, \{b_s\}) & \text{otherwise} \end{cases}$$

*Store-Load and Load-Load Eliminations.*

**Definition 28.**  $\mathcal{R}(G_s, G_t, m, a_t)$  — is a *simulation relation* for store-load and load-load elimination transformations, where  $G_s$  is a source graph,  $G_t$  is a target graph,  $m : G_t.E \rightarrow G_s.E$  is an event mapping function,  $a_t \in (W \uplus R)$  is an event in  $G_t$ , as follows

- $m$  is injective
- $G_s.tid \circ m = G_t.tid$
- $G_s.lab \circ m = G_t.lab$
- $G_s.E = m \uparrow G_t.E \cup \mathcal{B}_s$
- $G_s.po = m \uparrow G_t.po \cup \text{InsertAfter}(m \uparrow G_t.po, \mathcal{A}_s, \mathcal{B}_s)$
- $G_s.rf = m \uparrow G_t.rf \cup m \uparrow \text{WriteOf}(G_t, a_t) \times \mathcal{B}_s$
- $G_s.mo = m \uparrow G_t.mo$

where:

$$\begin{aligned} a_s &\triangleq m(a_t) \\ \mathcal{A}_s &\triangleq \{a_s\} \\ \mathcal{B}_s &\triangleq \begin{cases} \{b_s\} & \text{if } a_t \in G_t.E, \text{ where } b_s \text{ is an event, s.t. } \mathcal{P}(b_s) \text{ holds} \\ \emptyset & \text{otherwise} \end{cases} \\ \mathcal{P}(b_s) &\triangleq (G_s.op(b_s) = R \wedge G_s.loc(b_s) = G_s.loc(a_s) \wedge G_s.val(b_s) = G_s.val(a_s)) \end{aligned}$$

**Lemma 13.** Let  $G_t^{init}$  and  $G_s^{init}$  be initial execution graphs. Then  $\mathcal{R}(G_s^{init}, G_t^{init}, id, a_t, b_t)$  holds.

PROOF. Easy to see that  $\mathcal{B}_s = \emptyset$ , so the first four conditions of Definition 28 hold. As well as the rest of them, since the sets of *po*, *rf* and *mo* edges are empty for initial execution graphs and  $\mathcal{B}_s$  is once again empty. □

**Lemma 14.** Let  $G_t$  and  $G_s$  be  $\mathcal{M}$  consistent and assume  $\mathcal{R}(G_s, G_t, m, a_t)$  holds. If  $G_t \rightarrow G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \rightarrow^* G'_s$  and  $\mathcal{R}(G'_s, G'_t, m', a_t)$  also hold.

PROOF. We do a case analysis on  $G_t \rightarrow G'_t$  and use Lemmas 15 to 17 to derive  $G'_s$  and  $\mathcal{R}(G'_s, G'_t, m, a_t, b_t)$ .  $\square$

**Lemma 15.** Let  $G_t$  and  $G_s$  be  $\mathcal{M}$  consistent and assume  $\mathcal{R}(G_s, G_t, m, a_t)$  holds. If  $G_t \xrightarrow[e]{e \notin \{a_t\}} G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \xrightarrow[e]{m'(e)} G'_s$  and  $\mathcal{R}(G'_s, G'_t, m', a_t)$  also hold.

PROOF. Let us define  $e'$  as an event, s.t.  $\mathcal{P}_e(e')$  holds:

$$\mathcal{P}_e(e') \triangleq (G_s.\text{op}(e') = G_t.\text{op}(e) \wedge G_s.\text{loc}(e') = G_t.\text{loc}(e) \wedge G_s.\text{ord}(e') = G_t.\text{ord}(e))$$

Therefore, we can construct  $G'_s$  and  $m'$  as follows:

- $m' = m[e \mapsto e']$
- $G'_s.E = G_s.E \cup \{e'\}$
- $G'_s.\text{tid} = G_s.\text{tid}[e' \mapsto G'_t.\text{tid}(e)]$
- $G'_s.\text{lab} = G_s.\text{lab}[e' \mapsto G'_t.\text{lab}(e)]$
- $G'_s.\text{po} = G_s.\text{po} \cup m \uparrow G'_t.\text{po}; [\{e\}]$
- $G'_s.\text{rf} = G_s.\text{rf} \cup m \uparrow G'_t.\text{rf}; [\{e\} \cap G'_t.R]$
- $G'_s.\text{mo} = G_s.\text{mo} \cup m \uparrow [\{e\} \cap G'_t.W]; G'_t.\text{mo} \cup m \uparrow G'_t.\text{mo}; [\{e\} \cap G'_t.W]$
- $G'_s.\text{rmw} = m \uparrow G'_t.\text{rmw}$

From this construction and Definition 28, it follows immediately that  $\mathcal{R}(G'_s, G'_t, m', a_t)$  holds.

In case when  $\mathcal{B}_s$  is empty, consistency of the source graph,  $\text{Consistent}(\mathcal{M}, G'_s)$ , follows directly from the consistency of the target graph,  $\text{Consistent}(\mathcal{M}, G'_t)$ , due to monotonicity property Lemma 7. In the other case when  $\mathcal{B}_s \neq \emptyset$ , it follows from Lemma 11.  $\square$

**Lemma 16.** Let  $G_t$  and  $G_s$  be  $\mathcal{M}$  consistent and assume  $\mathcal{R}(G_s, G_t, m, a_t)$  holds. If  $G_t \xrightarrow[e]{a_t} G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \xrightarrow[e]{a_s} \xrightarrow[e]{b_s} G'_s$  holds, with  $a_s \triangleq m'(a_t)$ , and  $\mathcal{R}(G'_s, G'_t, m', a_t)$  also holds.

PROOF. We construct  $m'$  and  $G'_s$  as follows:

- $m' = m[a_t \mapsto a_s]$
- $G'_s.E = G_s.E \cup \{a_s\} \cup \{b_s\}$
- $G'_s.\text{tid} = G_s.\text{tid}[a_s \mapsto G'_t.\text{tid}(a_t)][b_s \mapsto G'_t.\text{tid}(a_t)]$
- $G'_s.\text{lab} = G_s.\text{lab}[a_s \mapsto G'_t.\text{lab}(a_t)][b_s \mapsto \ell]$
- $G'_s.\text{po} = G_s.\text{po} \cup \text{InsertAfter}(m \uparrow G_t.\text{po}, \{a_s\}, \{b_s\})$
- $G'_s.\text{rf} = G_s.\text{rf} \cup \text{WriteOf}(G_t, a_t) \times b_s$
- $G'_s.\text{mo} = G_s.\text{mo} \cup m \uparrow [\{a_t\} \cap G'_t.W]; G'_t.\text{mo} \cup m \uparrow G'_t.\text{mo}; [\{a_t\} \cap G'_t.W]$
- $G'_s.\text{rmw} = m \uparrow G'_t.\text{rmw}$

Where  $\ell$  is label for  $b_s$  such that:

$$G_s.\text{op}(b_s) = R \wedge G_s.\text{loc}(b_s) = G_s.\text{loc}(a_s) \wedge G_s.\text{val}(b_s) = G_s.\text{val}(a_s)$$

From this construction and Definition 28, it follows immediately that  $\mathcal{R}(G'_s, G'_t, m', a_t)$  holds.

The consistency of the source graph follows from same-read extensibility Lemma 11 applied to the intermediate source graph we get after adding  $a_s$ , which is consistent due to Definition 18.  $\square$

**Lemma 17.** *Let  $G_t$  and  $G_s$  be  $\mathcal{M}$  consistent and  $\mathcal{R}(G_s, G_t, m, a_t)$  holds. If  $G_t \xrightarrow[re-exec]{C} G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \xrightarrow[re-exec]{m' \uparrow C} G'_s$  holds, and  $\mathcal{R}(G'_s, G'_t, m', a_t)$  also holds.*

PROOF. We construct  $m'$  and  $G'_s$  as follows:

- $m' = \text{if } a_t \in G_t.E \text{ then id}[a_t \mapsto a_s] \text{ else id}$
- $G'_s.tid = G'_t.tid \circ m$
- $G'_s.lab = G'_t.lab \circ m$
- $G'_s.E = m \uparrow G'_t.E \cup \mathcal{B}_s$
- $G'_s.po = m \uparrow G'_t.po \cup \text{InsertAfter}(m \uparrow G_t.po, \mathcal{A}_s, \mathcal{B}_s)$
- $G'_s.rf = m \uparrow G'_t.rf \cup \text{WriteOf}(G_t, a_t) \times \mathcal{B}_s$
- $G'_s.mo = m \uparrow G'_t.mo$
- $G'_s.rmw = m \uparrow G'_t.rmw$

From this construction and Definition 28, it follows immediately that  $\mathcal{R}(G'_s, G'_t, m', a_t)$  holds. We will define the components of the re-execution step as follows:

- $C_s \triangleq m \uparrow C'_t \cup \text{if } a_t \in C_t \text{ then } \{b_t\} \text{ else } \emptyset$
- $\mathcal{D}_s \triangleq m \uparrow \mathcal{D}_t \cup \text{if } a_t \in \mathcal{D}_t \text{ then } \{b_t\} \text{ else } \emptyset$
- $f_s \triangleq m \circ f_t \circ m'^{-1}$

In both cases, the following properties follow immediately from definitions:

- $C_s \subseteq G'_s.E$
- $\mathcal{D}_s \subseteq C_s$
- $\text{dom}(G.po; [\mathcal{D}_s]) \subseteq \mathcal{D}_s$
- $\text{WellFormed}(G|_{\mathcal{D}_s}, G'_s, C_s)$
- $\text{CommitEmbedded}(G_s, G'_s, C_s, f_s)$

The property  $\text{dom}(G'_s.rpo; [G'_s.E \setminus \mathcal{D}_s]) \subseteq \mathcal{D}_s$  follows from the fact that  $G'_s.rpo \subseteq G'_t.rpo$  and the respective property of the target graph.

To prove  $\text{ThreadOrderedUEvents}(G', C_s, \prec_{tid})$  we use the following observation:

$$\begin{aligned} G'_s.vf; G'_s.\underset{tid}{=}; [\mathcal{U}_s] &= [G'_s.W]; G'_s.rf; G'_s.hb^?; G'_s.\underset{tid}{=}; [\mathcal{U}_s] \subseteq \\ &\subseteq m' \uparrow ([G'_t.W]; G'_t.rf; G'_t.hb^?; G'_t.\underset{tid}{=}; [\mathcal{U}_t]) \cup \\ &\cup G'_s.rf; [\mathcal{B}]; G'_s.po; (m' \uparrow G'_t.hb)^?; G'_s.\underset{tid}{=}; [\mathcal{U}_s] \cup \end{aligned}$$

- For the first disjunct, we notice that:

$$m' \uparrow ([G'_t.W]; G'_t.rf; G'_t.hb^?; G'_t.\underset{tid}{=}; [\mathcal{U}_t]) = m' \uparrow (G'_t.vf; G'_t.\underset{tid}{=}; [\mathcal{U}_t])$$

- For the second disjunct we can construct a similar path in  $G'_t$  to  $b_t$ , because  $a_s$  and  $b_s$  have the same set of outgoing  $hb$  edges (except  $\langle a_s, b_s \rangle$  edge):

$$\begin{aligned} [G'_s.W]; G'_s.rf[\mathcal{B}_s]; G'_s.po; (m \uparrow G'_t.hb)^?; G'_s.\underset{tid}{=}; [\mathcal{U}_s] &\subseteq \\ [G'_s.W]; G'_s.rf^?; [\mathcal{A}_s]; m \uparrow (G'_t.hb; G'_t.\underset{tid}{=}; [\mathcal{U}_t]) &\subseteq \\ m \uparrow (G'_t.vf; G'_t.\underset{tid}{=}; [\mathcal{U}_t]) & \end{aligned}$$

So in the result, we get the desired property:

$$G'_s.vf; G'_s.\underset{tid}{=}; [\mathcal{U}_s] \subseteq m \uparrow (G'_t.vf; G'_t.\underset{tid}{=}; [\mathcal{U}_t]) \subseteq m \uparrow (G'_t.tid \downarrow \preceq_{tid}) = G'_s.tid \downarrow \preceq_{tid}$$

In case when  $\mathcal{B}$  is empty, consistency of the source graph,  $\text{Consistent}(\mathcal{M}, G'_s)$ , follows directly from the consistency of the target graph,  $\text{Consistent}(\mathcal{M}, G'_t)$ , due to monotonicity property Lemma 7. And in the other case, it follows from same-read extensibility Lemma 11.

It is left to show that:

$$\langle G'_s, C_s \rangle \vdash G_s|_{\mathcal{D}_s} \Rightarrow^* G'_s$$

For this, we can apply Lemma 1 with  $\ell$  inherited from the target graph, adding the  $b_s$  event to the end of the list if needed.

□

**Lemma 18.** *Suppose that  $\mathcal{R}(G_s, G_t, m, a_t)$  holds. Then  $G_s$  is also  $\mathcal{M}$  consistent and terminal, and moreover  $\mathcal{M}(G_s, G_t, m, b_t)$  holds.*

PROOF.  $\mathcal{M}$  consistency follows from same-read extensibility property Lemma 11, since  $\mathcal{B}$  is not empty, and all the prerequisites are met from the  $\mathcal{R}(G_s, G_t, m, a_t)$  definition.  $\mathcal{M}(G_s, G_t, m, b_t)$  holds by the same reasoning. □

**Theorem 3.**

$$\begin{aligned} \forall \mathbb{P}_{\text{src}}. \text{elim}(\mathbb{P}_{\text{src}}, \mathbb{P}_{\text{tgt}}) &\implies \\ \forall G_t. G_{\text{init}} &\rightarrow^* G_t. \exists G_s. G_{\text{init}} \rightarrow^* G_s. \text{Behavior}(G_s) = \text{Behavior}(G_t) \end{aligned}$$

PROOF. We do induction on the construction steps:  $G_{\text{init}} \rightarrow^* G_t$ . We use Lemma 13 to show that initial graphs  $G_t^{\text{init}}$  and  $G_s^{\text{init}}$  are in simulation relation  $\mathcal{R}$ . Then using Lemma 14 we show that each step of the target graph construction  $G_t \rightarrow G'_t$  can be simulated by the source graph construction step  $G_s \rightarrow G'_s$ . Finally, we use lemma Lemma 18 to derive that the final graph  $G_s$  is  $\mathcal{M}$  consistent. □

*Store-Store Elimination.*

**Definition 29.**  $\mathcal{R}(G_s, G_t, m, b_t, v)$  — is a *simulation relation* for store-store elimination transformation, where  $G_s$  is a source graph,  $G_t$  is a target graph,  $m : G_t.E \rightarrow G_s.E$  is an event mapping function,  $b_t \in W$  is an event in  $G_t$ ,  $v \in \text{VAL}$  is a value, as follows

- $m$  is injective
- $G_s.\text{tid} \circ m = G_t.\text{tid}$
- $G_s.\text{lab} \circ m = G_t.\text{lab}$
- $G_s.E = m \upharpoonright G_t.E \cup \mathcal{A}_s$
- $G_s.\text{po} = m \upharpoonright G_t.\text{po} \cup \text{InsertBefore}(m \upharpoonright G_t.\text{po}, \mathcal{B}_s, \mathcal{A}_s)$
- $G_s.\text{rf} = m \upharpoonright G_t.\text{rf}$
- $G_s.\text{mo} = m \upharpoonright G_t.\text{mo} \cup \text{InsertBefore}(m \upharpoonright G_t.\text{mo}, \mathcal{B}_s, \mathcal{A}_s)$

where:

$$\begin{aligned} b_s &\triangleq m(b_t) \\ \mathcal{B}_s &\triangleq \{b_s\} \\ \mathcal{A}_s &\triangleq \begin{cases} \{a_s\} & \text{if } b_t \in G_t.E, \text{ where } a_s \text{ is an event, s.t. } \mathcal{P}(a_s) \text{ holds} \\ \emptyset & \text{otherwise} \end{cases} \\ \mathcal{P}(a_s) &\triangleq (G_s.\text{op}(a_s) = W \wedge G_s.\text{loc}(a_s) = G_s.\text{loc}(b_s) \wedge G_s.\text{val}(a_s) = v) \end{aligned}$$

**Lemma 19.** *Let  $G_t^{\text{init}}$  and  $G_s^{\text{init}}$  be initial execution graphs. Then  $\mathcal{R}(G_s^{\text{init}}, G_t^{\text{init}}, \text{id}, a_t, b_t)$  holds.*

PROOF. Easy to see that  $\mathcal{A}_s = \emptyset$ , so the first four conditions of Definition 29 hold. As well as the rest of them, since the sets of **po**, **rf** and **mo** edges are empty for initial execution graphs and  $\mathcal{A}_s$  is once again empty.  $\square$

**Lemma 20.** *Let  $G_t$  and  $G_s$  be  $\mathcal{M}$  consistent and assume  $\mathcal{R}(G_s, G_t, m, b_t, v)$  holds. If  $G_t \rightarrow G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \rightarrow^* G'_s$  and  $\mathcal{R}(G'_s, G'_t, m', b_t, v)$  also hold.*

PROOF. We do a case analysis on  $G_t \rightarrow G'_t$  and use Lemmas 21 to 23 to derive  $G'_s$  and  $\mathcal{R}(G'_s, G'_t, m', b_t, v)$ .  $\square$

**Lemma 21.** *Let  $G_t$  and  $G_s$  be  $\mathcal{M}$  consistent and assume  $\mathcal{R}(G_s, G_t, m, b_t, v)$  holds. If  $G_t \xrightarrow[\text{exec}]{e \notin \{b_t\}} G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \xrightarrow[\text{exec}]{m'(e)} G'_s$  and  $\mathcal{R}(G'_s, G'_t, m', b_t, v)$  also hold.*

PROOF. Let us define  $e'$  as an event, s.t.  $\mathcal{P}_e(e')$  holds:

$$\mathcal{P}_e(e') \triangleq (G_s.\text{op}(e') = G_t.\text{op}(e) \wedge G_s.\text{loc}(e') = G_t.\text{loc}(e) \wedge G_s.\text{ord}(e') = G_t.\text{ord}(e))$$

Therefore, we can construct  $G'_s$  and  $m'$  as follows:

- $m' = m[e \mapsto e']$
- $G'_s.E = G_s.E \cup \{e'\}$
- $G'_s.\text{tid} = G_s.\text{tid}[e' \mapsto G'_t.\text{tid}(e)]$
- $G'_s.\text{lab} = G_s.\text{lab}[e' \mapsto G'_t.\text{lab}(e)]$
- $G'_s.\text{po} = G_s.\text{po} \cup m \uparrow G'_t.\text{po}; [\{e\}]$
- $G'_s.\text{rf} = G_s.\text{rf} \cup m \uparrow G'_t.\text{rf}; [\{e\} \cap G'_t.R]$
- $G'_s.\text{mo} = G_s.\text{mo} \cup m \uparrow [\{e\} \cap G'_t.W]; G'_t.\text{mo} \cup m \uparrow G'_t.\text{mo}; [\{e\} \cap G'_t.W]$
- $G'_s.\text{rmw} = m \uparrow G'_t.\text{rmw}$

From this construction and Definition 29, it follows immediately that  $\mathcal{R}(G'_s, G'_t, m', b_t, v)$  holds.

In case when  $\mathcal{A}_s$  is empty, consistency of the source graph,  $\text{Consistent}(\mathcal{M}, G'_s)$ , follows directly from the consistency of the target graph,  $\text{Consistent}(\mathcal{M}, G'_t)$ , due to the monotonicity property Lemma 7. And in the other case, it follows from Lemma 10.  $\square$

**Lemma 22.** *Let  $G_t$  and  $G_s$  be  $\mathcal{M}$  consistent and assume  $\mathcal{R}(G_s, G_t, m, b_t, v)$  holds. If  $G_t \xrightarrow[\text{exec}]{a_t} G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \xrightarrow[\text{exec}]{a_s} \xrightarrow[\text{exec}]{b_s} G'_s$  holds, with  $a_s \triangleq m'(a_t)$ , and  $\mathcal{R}(G'_s, G'_t, m', b_t, v)$  also holds.*

PROOF. We construct  $m'$  and  $G'_s$  as follows:

- $m' = m[b_t \mapsto b_s]$
- $G'_s.E = G_s.E \cup \{a_s\} \cup \{b_s\}$
- $G'_s.\text{tid} = G_s.\text{tid}[a_s \mapsto G'_t.\text{tid}(b_t)][b_s \mapsto G'_t.\text{tid}(b_t)]$
- $G'_s.\text{lab} = G_s.\text{lab}[a_s \mapsto \ell][b_s \mapsto G'_t.\text{lab}(a_t)]$
- $G'_s.\text{po} = G_s.\text{po} \cup \text{InsertBefore}(m \uparrow G_t.\text{po}, \{b_s\}, \{a_s\})$
- $G'_s.\text{rf} = G_s.\text{rf}$
- $G'_s.\text{mo} = G_s.\text{mo} \cup \text{InsertBefore}(m \uparrow G_t.\text{mo}, \mathcal{B}_s, \mathcal{A}_s)$
- $G'_s.\text{rmw} = m \uparrow G'_t.\text{rmw}$

Where  $\ell$  is label for  $a_s$  such that:

$$G_s.\text{op}(a_s) = W \wedge G_s.\text{loc}(a_s) = G_s.\text{loc}(b_s) \wedge G_s.\text{val}(a_s) = v$$

From this construction and Definition 29, it follows immediately that  $\mathcal{R}(G'_s, G'_t, m', b_t, v)$  holds.

Consistency of the source graph follows from overwrite extensibility Lemma 10 applied to the intermediate source graph we get after adding  $a_s$ , which is consistent due to Lemma 7.  $\square$

**Lemma 23.** *Let  $G_t$  and  $G_s$  be  $\mathcal{M}$  consistent and  $\mathcal{R}(G_s, G_t, m, b_t, v)$  holds. If  $G_t \xrightarrow[\text{re-exec}]{C} G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \xrightarrow[\text{re-exec}]{m' \uparrow C} G'_s$  holds, and  $\mathcal{R}(G'_s, G'_t, m', b_t, v)$  also holds.*

PROOF. We construct  $m'$  and  $G'_s$  as follows:

- $m' = \text{if } b_t \in G_t.E \text{ then } \text{id}[b_t \mapsto b_s] \text{ else } \text{id}$
- $G'_s.\text{tid} = G'_t.\text{tid} \circ m$
- $G'_s.\text{lab} = G'_t.\text{lab} \circ m$
- $G'_s.E = m \uparrow G'_t.E \cup \mathcal{B}_s$
- $G'_s.\text{po} = m \uparrow G'_t.\text{po} \cup \text{InsertBefore}(m \uparrow G_t.\text{po}, \mathcal{B}_s, \mathcal{A}_s)$
- $G'_s.\text{rf} = m \uparrow G'_t.\text{rf}$
- $G'_s.\text{mo} = m \uparrow G'_t.\text{mo} \cup \text{InsertBefore}(m \uparrow G_t.\text{mo}, \mathcal{B}_s, \mathcal{A}_s)$
- $G'_s.\text{rmw} = m \uparrow G'_t.\text{rmw}$

From this construction and Definition 29, it follows immediately that  $\mathcal{R}(G'_s, G'_t, m', b_t, v)$  holds. We will define the components of the re-execution step as follows:

- $C_s \triangleq \uparrow C'_t$  **if**  $b_t \in C_t$  **then**  $\{a_t\}$  **else**  $\emptyset$
- $\mathcal{D}_s \triangleq m \uparrow \mathcal{D}'_t$  **if**  $b_t \in \mathcal{D}_t$  **then**  $\{a_t\}$  **else**  $\emptyset$
- $f_s \triangleq m \circ f_t \circ m'^{-1}$

In both cases, the following properties follow immediately from definitions:

- $C_s \subseteq G'_s.E$
- $\mathcal{D}_s \subseteq C_s$
- $\text{dom}(G.\text{po}; [\mathcal{D}_s]) \subseteq \mathcal{D}_s$
- $\text{WellFormed}(G|_{\mathcal{D}_s}, G'_s, C_s)$
- $\text{CommitEmbedded}(G_s, G'_s, C_s, f_s)$

The property  $\text{dom}(G'_s.\text{rpo}; [G'_s.E \setminus \mathcal{D}_s]) \subseteq \mathcal{D}_s$  follows from the fact that  $G'_s.\text{rpo} \subseteq G'_t.\text{rpo}$  and the respective property of the target graph.

To prove  $\text{ThreadOrderedUEvents}(G', C_s, \prec_{\text{tid}})$  we use the following observation:

$$\begin{aligned} G'_s.\text{vf}; G'_s.\text{rf}; G'_s.\text{hb}^?; G'_s.\text{mo}; G'_s.\text{rmw}; G'_s.\text{po}; G'_s.\text{tid} &= [G'_s.W]; G'_s.\text{rf}; G'_s.\text{hb}^?; G'_s.\text{mo}; G'_s.\text{rmw}; G'_s.\text{po}; G'_s.\text{tid} \\ &\subseteq m' \uparrow ([G'_t.W]; G'_t.\text{rf}; G'_t.\text{hb}^?; G'_t.\text{mo}; G'_t.\text{rmw}; G'_t.\text{po}; G'_t.\text{tid}) \cup \\ &\cup [\mathcal{A}]; G'_s.\text{po}; m' \uparrow (G'_t.\text{hb}^?; G'_t.\text{mo}; G'_t.\text{rmw}; G'_t.\text{tid}) \cup \end{aligned}$$

- For the first disjunct, we notice that:

$$m' \uparrow ([G'_t.W]; G'_t.\text{rf}; G'_t.\text{hb}^?; G'_t.\text{mo}; G'_t.\text{rmw}; G'_t.\text{tid}) = m' \uparrow (G'_t.\text{vf}; G'_t.\text{rf}; G'_t.\text{mo}; G'_t.\text{rmw}; G'_t.\text{tid})$$

- For the second disjunct we can construct a similar path in  $G'_t$  to  $b_t$ , because  $a_s$  and  $b_s$  have the same set of outgoing **hb** edges (except  $\langle a_s, b_s \rangle$  edge):

$$\begin{aligned} [\mathcal{A}]; G'_s.\text{po}; m' \uparrow (G'_t.\text{rf}^?; G'_t.\text{hb}^?; G'_t.\text{mo}; G'_t.\text{rmw}; G'_t.\text{tid}) &\subseteq \\ m' \uparrow ([\mathcal{B}]; G'_t.\text{po}; G'_t.\text{hb}^?; G'_t.\text{mo}; G'_t.\text{rmw}; G'_t.\text{tid}) &\subseteq \\ m \uparrow (G'_t.\text{vf}; G'_t.\text{rf}; G'_t.\text{mo}; G'_t.\text{rmw}; G'_t.\text{tid}) & \end{aligned}$$

So in the result, we get the desired property:

$$G'_s.\mathbf{vf}; G'_s.\mathbf{=}_{\text{tid}}; [\mathcal{U}_s] \subseteq m \uparrow (G'_t.\mathbf{vf}; G'_t.\mathbf{=}_{\text{tid}}; [\mathcal{U}_t]) \subseteq m \uparrow (G'_t.\text{tid} \downarrow \preceq_{\text{tid}}) = G'_s.\text{tid} \downarrow \preceq_{\text{tid}}$$

In case when  $\mathcal{B}$  is empty, consistency of the source graph,  $\text{Consistent}(\mathcal{M}, G'_s)$ , follows directly from the consistency of the target graph,  $\text{Consistent}(\mathcal{M}, G'_t)$ , due to monotonicity property Lemma 7. In the other case, it follows from overwrite extensibility Lemma 10.

It is left to show that:

$$\langle G'_s, C_s \rangle \vdash G_s | \mathcal{D}_s \Rightarrow^* G'_s$$

For this, we can apply Lemma 1 with  $\ell$  inherited from the target graph, adding the  $a_s$  event at the end of the list if needed.  $\square$

**Lemma 24.** *Suppose that  $\mathcal{R}(G_s, G_t, m, b_t, v)$  holds. Then  $G_s$  is also  $\mathcal{M}$  consistent and terminal, and moreover  $\mathcal{M}(G_s, G_t, m, a_t)$  holds.*

PROOF.  $\mathcal{M}$  consistency follows from overwrite extensibility property Lemma 10, since  $\mathcal{A}$  is not empty, and all the prerequisites are met from the  $\mathcal{R}(G_s, G_t, m, b_t, v)$  definition.  $\mathcal{M}(G_s, G_t, m, a_t)$  holds by the same reasoning.  $\square$

**Theorem 4.**

$$\begin{aligned} \forall \mathbb{P}_{\text{src}}. \text{elim}(\mathbb{P}_{\text{src}}, \mathbb{P}_{\text{tgt}}) &\implies \\ \forall G_t. G_{\text{init}} \rightarrow^* G_t. \exists G_s. G_{\text{init}} \rightarrow^* G_s. \text{Behavior}(G_s) &= \text{Behavior}(G_t) \end{aligned}$$

PROOF. We do induction on the construction steps:  $G_{\text{init}} \rightarrow^* G_t$ . We use Lemma 19 to show that initial graphs  $G_t^{\text{init}}$  and  $G_s^{\text{init}}$  are in simulation relation  $\mathcal{R}$ . Then using Lemma 20 we show that each step of the target graph construction  $G_t \rightarrow G'_t$  can be simulated by the source graph construction step  $G_s \rightarrow G'_s$ . Finally, we use lemma Lemma 24 to derive that the final graph  $G_s$  is  $\mathcal{M}$  consistent.  $\square$

## E.2 Reordering

We prove the soundness of the reordering transformation on the level of the execution graphs by reordering two adjacent events.

**Definition 30.** Let  $G_s$  and  $G_t$  be the source and the target execution graphs respectively, and let  $m : G_t.E \rightarrow G_s.E$  be an event mapping function. We say that events  $a, b \in G_t.E$  form a reordering pair

$$a \cdot b \rightsquigarrow b \cdot a$$

if the following conditions are met:

- $G_t.\text{loc}(a) \neq G_t.\text{loc}(b)$
- $G_s.\text{lab}(m(a)) = G_t.\text{lab}(a)$
- $G_s.\text{lab}(m(b)) = G_t.\text{lab}(b)$
- $m \uparrow \langle b, a \rangle \in G_s.\text{po}_{\text{imm}}$
- $\langle b, a \rangle \in G_t.\text{po}_{\text{imm}}$
- $\langle b, a \rangle \notin G_t.\text{rpo}$

**Definition 31.** We define a relation  $\mathcal{M}(G_s, G_t, m, a, b)$  asserting that the target graph  $G_t$  is obtained as a result of applying the reordering transformation to the source graph  $G_s$ , where  $m : G_t.E \rightarrow G_s.E$  is an event mapping function,  $a$  and  $b$  are reordered events in  $G_t$ :

- $m$  is injective
- $G_s.E = m \uparrow G_t.E$
- $G_s.\text{tid} \circ m = G_t.\text{tid}$

- $G_s.\text{lab} \circ m = G_t.\text{lab}$
- $G_s.\text{po} = m \uparrow \text{Swap}(R, \{b\}, \{a\})$
- $G_s.\text{rf} = m \uparrow G_t.\text{rf}$
- $G_s.\text{mo} = m \uparrow G_t.\text{mo}$
- $G_s.\text{rmw} = m \uparrow G_t.\text{rmw}$

**Definition 32.**  $\mathcal{R}(G_s, G_t, m, a_t, b_t)$  — is a *simulation relation* for the reordering transformation where  $G_s$  is a source graph,  $G_t$  is a target graph, and  $m : G_t.E \rightarrow G_s.E$  is an event mapping function, and  $a_t$  and  $b_t$  are reordered events in  $G_t$ .

- $m$  is injective
- $G_s.E = m \uparrow G_t.E \cup \mathcal{A}_s$
- $G_s.\text{tid} \circ m = G_t.\text{tid}$
- $G_s.\text{lab} \circ m = G_t.\text{lab}$
- $G_s.\text{po} = m \uparrow (\text{Swap}(R, \{b_t\}, \{a_t\}) \cup m \uparrow (\text{dom}(G_t.\text{po}; [b_t]) \times \{\mathcal{A}\}))$
- $G_s.\text{rf} = m \uparrow G_t.\text{rf} \cup G_s.\text{rrf}; [\mathcal{A}_s \cap R]$
- $G_s.\text{mo} = m \uparrow G_t.\text{mo} \cup (G_s.W_\ell \setminus \mathcal{A}_s) \times (\mathcal{A}_s \cap W)$
- $G_s.\text{rmw} = m \uparrow G_t.\text{rmw}$

where:

$$\begin{aligned} \ell &\triangleq G_t.\text{loc}(a_t) \\ b_s &\triangleq m(b_t) \\ \mathcal{A}_s &\triangleq \begin{cases} \{a'_s\} & \text{if } a_t \notin G_t.E \wedge b_t \in G_t.E, \quad \text{where } a'_s \text{ is an event, s.t. } \mathcal{P}(a'_s) \text{ holds} \\ \emptyset & \text{otherwise} \end{cases} \\ \mathcal{P}(a'_s) &\triangleq (G_s.\text{op}(a'_s) = G_t.\text{op}(a_t) \wedge G_s.\text{loc}(a'_s) = G_t.\text{loc}(a_t) \wedge G_s.\text{ord}(a'_s) = G_t.\text{ord}(a_t)) \end{aligned}$$

**Lemma 25.** Let  $G_t^{\text{init}}$  and  $G_s^{\text{init}}$  be initial execution graphs. Then  $\mathcal{R}(G_s^{\text{init}}, G_t^{\text{init}}, \text{id}, a_t, b_t)$  holds.

PROOF. Easy to see that  $\mathcal{A}_s = \emptyset$ , so the first four conditions of Definition 32 hold. As well as the rest of them, since the sets of  $\text{po}_{\text{imm}}$ ,  $\text{rf}$ , and  $\text{mo}$  edges are empty for initial execution graphs and  $\mathcal{A}_s$  is once again empty.  $\square$

**Lemma 26.** Let  $G_t$  and  $G_s$  be  $\mathcal{M}$  consistent and assume  $\mathcal{R}(G_s, G_t, m, a_t, b_t)$  holds. If  $G_t \rightarrow G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \rightarrow^* G'_s$  and  $\mathcal{R}(G'_s, G'_t, m', a_t, a_t)$  also hold.

PROOF. We do a case analysis on  $G_t \rightarrow G'_t$  and use Lemmas 27 to 30 to derive  $G'_s$  and  $\mathcal{R}(G'_s, G'_t, m, a_t, b_t)$ .  $\square$

**Lemma 27.** Let  $G_t$  and  $G_s$  be  $\mathcal{M}$  consistent and  $\mathcal{R}(G_s, G_t, m, a_t, b_t)$  holds. If  $G_t \xrightarrow[\text{exec}]{e_t \notin \{a_t, b_t\}} G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \xrightarrow[\text{exec}]{m'(e_t)} G'_s$  and  $\mathcal{R}_{rw}(G'_s, G'_t, m', a_t, b_t)$  also hold.

PROOF. Let us define  $e_s$  as an event, s.t.  $\mathcal{P}_e(e_s)$  holds:

$$\mathcal{P}_e(e_s) \triangleq (G_s.\text{op}(e_s) = G_t.\text{op}(e_t) \wedge G_s.\text{loc}(e_s) = G_t.\text{loc}(e_t) \wedge G_s.\text{ord}(e_s) = G_t.\text{ord}(e_t))$$

Therefore, we can construct  $G'_s$  and  $m'$  as follows:

- $m' = m[e_t \mapsto e_s]$
- $G'_s.E = G_s.E \cup \{e_s\}$
- $G'_s.\text{tid} = G_s.\text{tid}[e_s \mapsto G'_t.\text{tid}(e_t)]$

- $G'_s.\text{lab} = G_s.\text{lab}[e_s \mapsto G'_t.\text{lab}(e_t)]$
- $G'_s.\text{po} = G_s.\text{po} \cup m \uparrow (\text{dom}(G_t.\text{po}; [\{e_t\}]) \times \{e_s\})$
- $G'_s.\text{rf} = G_s.\text{rf} \cup m \uparrow G'_t.\text{rf}; [\{e_t\} \cap G'_t.R]$
- $G'_s.\text{mo} = G_s.\text{mo} \cup m \uparrow ([W_t]; G'_t.\text{mo}) \cup m(\uparrow G'_t.\text{mo}); [W_t] \cup (m \uparrow W_t) \times (\mathcal{A}_s \cap G_s.W_{\text{loc}(w)})$   
where  $W_t = \{e_t\} \cap G'_t.W$ .
- $G'_s.\text{rmw} = G_s.\text{rmw} \cup \text{if } \text{IsExclusiveWrite}(e_t) \uparrow G'_t.\text{rmw}; [\{e_t\}] \text{ else } \emptyset$

From this construction and Definition 32, it follows immediately that  $\mathcal{R}(G'_s, G'_t, m', a_t, b_t)$  holds. In case when  $\mathcal{A}_s$  is empty, consistency of the source graph,  $\text{Consistent}(\mathcal{M}, G'_s)$ , follows directly from the consistency of the target graph,  $\text{Consistent}(\mathcal{M}, G'_t)$ , due to monotonicity property Lemma 7. And in the other case, it follows from Lemma 8 if  $a_t$  is a read event, and from Lemma 9 if  $a_t$  is a write event. We apply these lemmas for graphs  $G'_t$  and  $G'_s$ , and the event  $a'_s$ .  $\square$

**Lemma 28.** *Let  $G_t$  and  $G_s$  be  $\mathcal{M}$  consistent and  $\mathcal{R}(G_s, G_t, m, a_t, b_t)$  holds. If  $G_t \xrightarrow[b_t]{b_t} G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \xrightarrow[b_s]{a'_s} G'_s$  holds, with  $b_s \triangleq m'(b_t)$ , and  $\mathcal{R}(G'_s, G'_t, m', a, b)$  also holds.*

PROOF. We construct  $m'$  and  $G'_s$  as follows:

- $m' = m[b_t \mapsto b_s]$
- $G'_s.E = G_s.E \cup \{a'_s\} \cup \{b_s\}$
- $G'_s.\text{tid} = G_s.\text{tid}[b_s \mapsto G'_t.\text{tid}(b_t)]$
- $G'_s.\text{lab} = G_s.\text{lab}[b_s \mapsto G'_t.\text{lab}(b_t)]$
- $G'_s.\text{po} = G_s.\text{po} \cup m \uparrow (\text{dom}(G_t.\text{po}; [\{b_t\}])) \times \{a'_s\} \cup \{\langle b_s, a'_s \rangle\}$
- $G'_s.\text{rf} = G_s.\text{rf} \cup m \uparrow G'_t.\text{rf}; [\{b_t\} \cap G'_t.R] \cup \{w_t\} \times \{a'_s\}$
- $G'_s.\text{mo} = G_s.\text{mo} \cup m \uparrow [\{b_t\} \cap G'_t.W]; G'_t.\text{mo} \cup m \uparrow G'_t.\text{mo}; [\{b_t\} \cap G'_t.W] \cup G_s.W \times \{a'_s\}$
- $G'_s.\text{rmw} = m \uparrow G'_t.\text{rmw}$

Where  $w_s$  is the  $G_s.\text{mo}$  maximal write event to the same location as  $G_s.\text{loc}(a'_s)$  from the view-front  $G_s.\text{vf}$  of the  $G_s.\text{po}$  maximal event of the thread  $G_s.\text{tid}(a'_s)$ . This ensures that we have an  $\text{srf}$ -edge from  $w_s$  to  $a'_s$ :  $G_s.\text{rf}; [\{a'_s\}] = G_s.\text{srf}; [\{a'_s\}]$ .

From this construction and Definition 32, it follows immediately that  $\mathcal{R}(G'_s, G'_t, m', a_t, b_t)$  holds.

Consistency of the source graph,  $\text{Consistent}(\mathcal{M}, G'_s)$ , follows from Lemma 8 if  $a_t$  is a read event, and from Lemma 9 if  $a_t$  is a write event. We apply these lemmas for graphs  $G'_t$  and  $G'_s$ , and the event  $a'_s$ .  $\square$

**Lemma 29.** *Let  $G_t$  and  $G_s$  be  $\mathcal{M}$  consistent and  $\mathcal{R}(G_s, G_t, m, a_t, b_t)$  holds. If  $G_t \xrightarrow[a_t]{a_t} G'_t$  holds there exists  $G'_s$ ,  $m'$ , and  $C$  such that  $G_s \xrightarrow[C]{re-exec} G'_s$  and  $\mathcal{R}(G'_s, G'_t, m', a_t, b_t)$  hold.*

PROOF. We construct  $m' \triangleq m$  and  $G'_s$  such that:

- $m' = m[a_t \mapsto a_s]$
- $G'_s.E = (G_s.E \setminus \{a'_s\}) \cup \{a_s\}$
- $G'_s.\text{tid} = G_s.\text{tid}[a'_s \mapsto \perp][a_s \mapsto G'_t.\text{tid}(a)]$
- $G'_s.\text{lab} = G_s.\text{lab}[a'_s \mapsto \perp][a_s \mapsto G'_t.\text{lab}(a)]$
- $G'_s.\text{po} = m \uparrow \text{Swap}(R, \{b\}, \{a\})$
- $G'_s.\text{rf} = G_s.\text{rf}; [G_s.E \setminus \{a'_s\}] \cup m \uparrow G'_t.\text{rf}; [\{a_t\} \cap G'_t.R]$
- $G'_s.\text{mo} = G_s.\text{mo}|_{G_s.E \setminus \{a'_s\}} \cup m \uparrow [\{a_t\} \cap G'_t.W]; G'_t.\text{mo} \cup m \uparrow G'_t.\text{mo}; [\{a_t\} \cap G'_t.W]$
- $G'_s.\text{rmw} = m \uparrow G'_t.\text{rmw}$

From this construction and Definition 32, it follows immediately that  $\mathcal{R}(G'_s, G'_t, m', a_t, b_t)$  holds.

We set  $C$ ,  $\mathcal{D}$ , and  $f$  as follows:

- $C \triangleq G'_s.E \setminus \{a_s\}$
- $\mathcal{D} \triangleq G_s.E \setminus \{a'_s, b_s\}$
- $f \triangleq \text{id}$

The following properties follow immediately from these definitions:

- $C \subseteq G'_s.E$
- $\mathcal{D} \subseteq \text{id} \uparrow C = C$
- $\text{dom}(G.\text{po}; [\mathcal{D}]) \subseteq \mathcal{D}$
- $\text{WellFormed}(G|_{\mathcal{D}}, G', C)$
- $\text{CommitEmbedded}(G, G', C, f)$

Because we re-execute only a single thread, the predicate  $\text{ThreadOrderedUEvents}(G', C, \prec_{\text{tid}})$  holds due to Corollary 2.

Consistency of the source graph,  $\text{Consistent}(\mathcal{M}, G'_s)$ , follows directly from the consistency of the target graph,  $\text{Consistent}(\mathcal{M}, G'_t)$ , due to the monotonicity property Definition 18.

It is left to show that:  $\langle G'_s, C \rangle \vdash G_s|_{\mathcal{D}} \Rightarrow^* G'_s$ . Here we note that we only re-execute a single thread, and thus the re-execution is possible due to Corollary 3. □

**Lemma 30.** *Let  $G_t$  and  $G_s$  be  $\mathcal{M}$  consistent and  $\mathcal{R}(G_s, G_t, m, a_t, b_t)$  holds. If  $G_t \xrightarrow[\text{re-exec}]{C} G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \xrightarrow[\text{re-exec}]{m' \uparrow C} G'_s$  holds, and  $\mathcal{R}(G'_s, G'_t, m', a_t, b_t)$  also holds.*

PROOF. Consider the cases.

(A.)  $b_t, a_t \notin G'_t.E_t$  or  $b_t, a_t \in G'_t.E_t$ . In this case we set:

- $m' = \text{id}$
- $G'_s.E = G'_t.E$
- $G'_s.\text{po} = m \uparrow (\text{Swap}(R, \{b_t\}, \{a_t\}) \cup m \uparrow (\text{dom}(G_t.\text{po}; [b_t]) \times \{\mathcal{A}\}))$
- $G'_s.\text{Rel} = m \uparrow G'_t.\text{Rel}$  for  $\text{Rel} \in \{\text{rf}, \text{mo}, \text{rmw}\}$
- $C_s \triangleq m' \uparrow C_t$
- $\mathcal{D}_s \triangleq m' \uparrow \mathcal{D}_t$
- $f_s \triangleq f_t$
- $f_s \triangleq m \circ f_t \circ m'^{-1}$

To show that the re-execution sequence  $\langle G'_s, C \rangle \vdash G_s|_{\mathcal{D}} \Rightarrow^* G'_s$ , despite the reordering of one program edge, we first apply Lemma 2 to sort the list  $\ell_t$ , and then apply Lemma 1 to the list  $\ell_s$  which is the same list as  $\ell_t$ , except  $b_s$  and  $a_s$  being possibly reordered.

The consistency of  $G'_s$  follows from Lemma 7.

Almost all of the other constraints of the re-execution step hold trivially, as well as simulation relation  $\mathcal{R}(G'_s, G'_t, m', a_t, b_t)$ . Indeed, in this case both graphs are almost equal except potentially one program order edge being swapped, but most of the constraints are invariant under this change.

As such, in this case  $G_s \xrightarrow[\text{re-exec}]{m' \uparrow C} G'_s$  and  $\mathcal{R}(G'_s, G'_t, m', a_t, b_t)$  also hold.

(B.)  $b_t \in G'_t.E_t, a_t \notin G'_t.E_t$  and  $b_t \in G'_t.\mathcal{T}$ . In this case, we construct  $m'$  and  $G'_s$  as follows ( $a'_s$  and  $\mathcal{A}$  are defined similarly as in Definition 32):

- $m' = \lambda e. \text{if } e \neq a'_s \text{ then } e \text{ else } \perp$
- $G'_s.E = m \uparrow G'_t.E \cup \mathcal{A}_s$
- $G'_s.\text{tid} = G'_t.\text{tid} \circ m$
- $G'_s.\text{lab} = G'_t.\text{lab} \circ m$

- $G_s.\text{po} = m \uparrow (\text{Swap}(R, \{b_t\}, \{a_t\}) \cup m \uparrow (\text{dom}(G_t.\text{po}; [b_t]) \times \{\mathcal{A}\}))$
- $G'_s.\text{rf} = m \uparrow G'_t.\text{rf} \cup G'_s.\text{srf}; [\mathcal{A}_s \cap R]$
- $G'_s.\text{mo} = m \uparrow G'_t.\text{mo} \cup G'_s.W_\ell \times (\mathcal{A}_s \cap W)$
- $G'_s.\text{rmw} = m \uparrow G'_t.\text{rmw}$

From this construction and Definition 32, it follows immediately that  $\mathcal{R}(G'_s, G'_t, m', a_t, b_t)$  holds. Next we set:

- $C_s \triangleq m \uparrow C_t$
- $\mathcal{D}_s \triangleq m \uparrow \mathcal{D}_t$
- $f_s \triangleq m \circ f_t \circ m'^{-1}$

The following properties follow immediately from definitions, as committed and determined sets coincide in the source and target graphs:

- $C_s \subseteq G'_s.E$
- $\mathcal{D}_s \subseteq C_s$
- $\text{dom}(G.\text{po}; [\mathcal{D}_s]) \subseteq \mathcal{D}_s$
- $\text{WellFormed}(G|_{\mathcal{D}_s}, G'_s, C_s)$
- $\text{CommitEmbedded}(G_s, G'_s, C_s, f_s)$

The property  $\text{dom}(G'_s.\text{rpo}; [G'_s.E \setminus \mathcal{D}_s]) \subseteq \mathcal{D}_s$  follows from the fact that  $G'_s.\text{rpo} \subseteq G'_t.\text{rpo}$  and the respective property of the target graph.

The consistency of the source graph follows from Lemma 8 if  $a_t$  is a read event, and from Lemma 9 if  $a_t$  is a write event.

To prove  $\text{ThreadOrderedUEvents}(G', C, <_{\text{tid}})$  we use the following observation:

$$\begin{aligned}
 G'_s.\text{vf}; G'_{s,\text{tid}}.; [\mathcal{U}_s] &= [G'_s.W]; G'_s.\text{rf}^2; G'_s.\text{hb}^2; G'_{s,\text{tid}}.; [\mathcal{U}_s] \subseteq \\
 &\subseteq m' \uparrow ([G'_t.W]; G'_t.\text{rf}^2; G'_t.\text{hb}^2; G'_{t,\text{tid}}.; [\mathcal{U}_s] \setminus \{\langle b_t, a_t \rangle\}; G'_{t,\text{tid}}.; [\mathcal{U}_t]) \cup \\
 &\cup G'_s.\text{rf}; G'_s.\text{hb}; [\mathcal{A}_s]; G'_{s,\text{tid}}.; [\mathcal{U}_s] \cup \\
 &\cup G'_s.\text{srf}; [\mathcal{A}_s]; G'_s.\text{rhb}; G'_{s,\text{tid}}.; [\mathcal{U}_s] \cup \\
 &\cup G'_s.\text{srf}; [\mathcal{A}_s]; G'_s.\text{po}^2; G'_{s,\text{tid}}.; [\mathcal{U}_s]
 \end{aligned}$$

- For the first disjunct, we notice that:

$$m' \uparrow ([G'_t.W]; G'_t.\text{rf}; G'_t.\text{hb}^2 \setminus \{\langle b_t, a_t \rangle\}; G'_{t,\text{tid}}.; [\mathcal{U}_t]) = m' \uparrow G'_t.\text{vf}; G'_{t,\text{tid}}.; [\mathcal{U}_t]$$

- For the second disjunct we can construct a similar path in  $G'_t$  to  $b_t$ , because  $a'_s$  and  $b_s$  have the same set of incoming **hb** edges (except  $\langle a'_s, b_s \rangle$  edge):

$$\begin{aligned}
 [G'_s.W]; G'_s.\text{rf}; G'_s.\text{hb}; [\mathcal{A}_s]; G'_{s,\text{tid}}.; [\mathcal{U}_s] &= \\
 &= m' \uparrow [G'_t.W]; G'_t.\text{rf}; G'_t.\text{hb}; [b_t]; G'_{t,\text{tid}}.; [\mathcal{U}_t] \subseteq \\
 &\subseteq m' \uparrow (G'_t.\text{vf}; G'_{t,\text{tid}}.; [\mathcal{U}_t])
 \end{aligned}$$

- For the third disjunct, we notice that  $[\mathcal{A}_s]; G'_s.\text{rhb} = \emptyset$  since  $a'_s$  is a **rhb** maximal event; and thus the whole disjunct is empty.
- For the last case of we first prove the following statement:

$$G'_s.\text{rhb} \subseteq G'_s.\text{po} \cup [\mathcal{D}_s]; G'_s.\text{rhb} \cup G'_s.\text{sw}; G'_s.\text{rhb}^2$$

by using the fact that **rhb**  $\subseteq$  **po**  $\cup$  **po**<sup>2</sup>; **sw**; **rhb**<sup>2</sup> and also property **po**; **sw** = **rpo**; **sw** (Proposition 1), and the fact that  $\text{dom}(G'_s.\text{rpo}; [G'_s.E \setminus \mathcal{D}_s]) \subseteq \mathcal{D}_s$ .

Using that  $\text{sr}\text{f} \subseteq \text{v}\text{f}$ ; po we next arrive at the following equation:

$$G'_s.\text{sr}\text{f}; [\mathcal{A}_s]; G'_s.\text{po}^? \subseteq m' \uparrow G'_t.\text{v}\text{f}; G'_s.\text{po}; [\mathcal{A}]; (\mathcal{A} \times \{b_t\})^? \subseteq m' \uparrow (G'_t.\text{v}\text{f}; G'_{t,\text{tid}}.; [\{b_t\}])$$

So in the result, we get the desired property:

$$m' \uparrow (G'_s.\text{v}\text{f}; G'_{s,\text{tid}}.; [\mathcal{U}_s]) \subseteq m' \uparrow (G'_t.\text{v}\text{f}; G'_{t,\text{tid}}.; [\mathcal{U}_t]) \subseteq m' \uparrow (G'_t.\text{tid} \downarrow \leq_{\text{tid}}) = G'_s.\text{tid} \downarrow \leq_{\text{tid}}$$

To show that:

$$\langle G'_s, C_s \rangle \vdash G_s|_{\mathcal{D}_s} \Rightarrow^* G'_s$$

we first apply Lemma 2 to sort  $\ell_t$ , and then apply Lemma 1 to the list  $\ell_s$  which is the same list as  $\ell_t$  but with an additional event  $a'_s$  inserted before  $b_t$ .

As such, in this case  $G_s \xrightarrow[\text{re-exec}]{m' \uparrow C} G'_s$  and  $\mathcal{R}(G'_s, G'_t, m', a_t, b_t)$  also hold.

(C.)  $b_t \in G'_t.E_t$ ,  $a_t \notin G'_t.E_t$  and  $b_t \notin G'_t.\mathcal{T}$ .

In this case, it has to be that  $b_t \in \mathcal{D}_t$ , and thus  $b_t \in G_t.E$  and it is the po last event in its thread.

It means that  $a'_s \in G_s.E$ .

We then show that it is possible to perform the re-execution:  $G_s \xrightarrow[\text{re-exec}]{C_s} G'_s$  where:

- $m' = \text{id}$
- $G'_s.E = m \uparrow G'_t.E \cup \{a'_s\}$
- $G'_s.\text{po} = m \uparrow G'_t.E \cup m \uparrow (\text{dom}(G_t.\text{po}; [b_t]) \times \{a'_s\}) \cup \{\langle a'_s, b_t \rangle\}$
- $G'_s.\text{rf} = m \uparrow G'_t.\text{rf}|_{G'_s.E} \cup G_s.\text{sr}\text{f}; [\{a'_s\}]$
- $G'_s.\text{Rel} = m \uparrow G'_t.\text{Rel}|_{G'_s.E}$  for  $\text{Rel} \in \{\text{rf}, \text{mo}, \text{rmw}\}$
- $C_s \triangleq m' \uparrow C_t \cup \{a'_s\}$
- $\mathcal{D}_s \triangleq m' \uparrow \mathcal{D}_t \cup \{a'_s\}$
- $f_s \triangleq m \circ f_t \circ m'^{-1}$

It is indeed possible to commit  $a'_s$  as the write it reads from belongs to  $C_s$ . We are using the following equation to demonstrate this:

$$\begin{aligned} \text{sr}\text{f}_s; [a'_s] &\subseteq (\text{po}_s \cup \text{rf}_s; \text{po}_s \cup \text{rf}_s^?; \text{r}\text{h}\text{b}_s); [a'_s] \subseteq \\ &\subseteq [\mathcal{D}_s]; \text{po}_s \cup [C_s]; \text{rf}_s; [\mathcal{D}_s]; \text{po}_s \cup [\mathcal{D}_s]; \text{rf}_s^?; [\mathcal{D}_s]; \text{r}\text{h}\text{b}_s \end{aligned}$$

From this construction and Definition 32, it follows immediately that  $\mathcal{R}(G'_s, G'_t, m', a_t, b_t)$  holds.

The following properties follow immediately from definitions, as committed and determined sets coincide in the source and target graphs:

- $C_s \subseteq G'_s.E$
- $\mathcal{D}_s \subseteq C_s$
- $\text{dom}(G.\text{po}; [\mathcal{D}_s]) \subseteq \mathcal{D}_s$
- $\text{WellFormed}(G|_{\mathcal{D}_s}, G'_s, C_s)$
- $\text{CommitEmbedded}(G_s, G'_s, C_s, f_s)$

The property  $\text{dom}(G'_s.\text{rpo}; [G'_s.E \setminus \mathcal{D}_s]) \subseteq \mathcal{D}_s$  follows from the fact that  $G'_s.\text{rpo} \subseteq G'_t.\text{rpo}$  and the respective property of the target graph.

The consistency of the source graph follows from Lemma 8 if  $a'_{s_t}$  is a read event, and from Lemma 9 if  $a'_{s_t}$  is a write event.

To prove  $\text{ThreadOrderedUEvents}(G', C, \prec_{\text{tid}})$  we use the same observation as in the previous case:

$$\begin{aligned}
G'_s.\text{vf}; G'_s.\text{=}_{\text{tid}}; [\mathcal{U}_s] &= [G'_s.W]; G'_s.\text{rf}^2; G'_s.\text{hb}^2; G'_s.\text{=}_{\text{tid}}; [\mathcal{U}_s] \subseteq \\
&\subseteq m' \uparrow ([G'_t.W]; G'_t.\text{rf}^2; G'_t.\text{hb}^2; G'_s.\text{=}_{\text{tid}}; [\mathcal{U}_s] \setminus \{\langle b_t, a_t \rangle\}; G'_t.\text{=}_{\text{tid}}; [\mathcal{U}_t]) \cup \\
&\cup G'_s.\text{rf}; G'_s.\text{hb}; [\mathcal{A}_s]; G'_s.\text{=}_{\text{tid}}; [\mathcal{U}_s] \cup \\
&\cup G'_s.\text{srf}; [\mathcal{A}_s]; G'_s.\text{rhh}; G'_s.\text{=}_{\text{tid}}; [\mathcal{U}_s] \cup \\
&\cup G'_s.\text{srf}; [\mathcal{A}_s]; G'_s.\text{po}^2; G'_s.\text{=}_{\text{tid}}; [\mathcal{U}_s]
\end{aligned}$$

The last three disjuncts are empty, since  $a'_s$  does not belong to the re-executed threads, i.e.,  $[\mathcal{A}_s]; G'_s.\text{=}_{\text{tid}}; [\mathcal{U}_s] = \emptyset$ , because neither do  $b_t$  by the assumption of this case:  $b_t \notin G'_t.\mathcal{T}$ . For the first disjunct, we use the same equations as in the previous case, arriving at:

$$G'_s.\text{vf}; G'_s.\text{=}_{\text{tid}}; [\mathcal{U}_s] \subseteq m' \uparrow (G'_t.\text{vf}; G'_t.\text{=}_{\text{tid}}; [\mathcal{U}_t]) \subseteq m' \uparrow (G'_t.\text{tid} \downarrow \preceq_{\text{tid}}) = G'_s.\text{tid} \downarrow \preceq_{\text{tid}}$$

It is left to show that:

$$\langle G_s, C_s \rangle \vdash G_s \Rightarrow^* G'_s$$

For this, we first apply Lemma 2 to sort  $\ell_t$ , and then apply Lemma 1 to the list  $\ell_s$  which is the same list as  $\ell_t$  but with an additional event  $a'_s$  inserted before  $b_t$ .

As such, in this case  $G_s \xrightarrow[\text{re-exec}]{m' \uparrow C} G'_s$  and  $\mathcal{R}(G'_s, G'_t, m', a_t, b_t)$  also hold.  $\square$

**Lemma 31.** Suppose that  $\mathcal{R}(G_s, G_t, m, a_t, b_t)$  holds, and  $G_t$  is  $\mathcal{M}$  consistent and terminal. Then  $G_s$  is also  $\mathcal{M}$  consistent and terminal, and moreover  $\mathcal{M}(G_s, G_t, m, a_t, b_t)$  holds.

PROOF.  $\mathcal{M}$  consistency follows from monotonicity property Definition 18, since  $\mathcal{A}_s$  is empty, and all the prerequisites are met from the  $\mathcal{R}(G_s, G_t, m, a_t, b_t)$  definition.  $\mathcal{M}(G_s, G_t, m, a_t, b_t)$  holds by the same reasoning.  $\square$

### Theorem 5.

$$\begin{aligned}
&\forall \mathbb{P}_{\text{src}}. \text{reord}(\mathbb{P}_{\text{src}}, \mathbb{P}_{\text{tgt}}) \implies \\
&\forall G_t. G_{\text{init}} \rightarrow^* G_t. \exists G_s. G_{\text{init}} \rightarrow^* G_s. \text{Behavior}(G_s) = \text{Behavior}(G_t)
\end{aligned}$$

PROOF. We do induction on the construction steps:  $G_{\text{init}} \rightarrow^* G_t$ . We use Lemma 25 to show that initial graphs  $G_t^{\text{init}}$  and  $G_s^{\text{init}}$  are in simulation relation  $\mathcal{R}$ . Then using Lemma 26 we show that each step of the target graph construction  $G_t \rightarrow G'_t$  can be simulated by the source graph construction step  $G_s \rightarrow G'_s$ . Finally, we use lemma Lemma 31 to derive that the final graph  $G_s$  is  $\mathcal{M}$  consistent.  $\square$

### E.3 Sequentialization

**Definition 33.**  $\mathcal{R}(G_s, G_t, m, t_1, t_2)$  — is a *simulation relation* for the sequentialization transformation, where  $G_s$  is a source graph,  $G_t$  is a target graph, and  $m : G_t.E \rightarrow G_s.E$  is an event mapping function, and  $G_s.t_1$  events are appended before the  $t_2$  events in  $G_t$ .

- $m$  is injective
- $G_t.\text{tid} = |_{\neq t_2} G_s.\text{tid} \circ m$
- $\forall e. G_s.\text{tid}(m(e)) = t_2 \implies G_t.\text{tid}(e) = t_1$
- $G_t.\text{lab} = G_s.\text{lab} \circ m$
- $m \uparrow G_t.E = G_s.E$

- $m \uparrow G_t.\text{po} = G_s.\text{po} \cup \text{po}_{seq}$
- $m \uparrow G_t.\text{rf} = G_s.\text{rf}$
- $m \uparrow G_t.\text{mo} = G_s.\text{mo}$

where:

$$\text{po}_{seq} \triangleq \{(a, b) \mid G_s.\text{tid}(a) = t_1 \wedge G_s.\text{tid}(b) = t_2\}$$

**Lemma 32.** *Let  $G_t^{\text{init}}$  and  $G_s^{\text{init}}$  be initial execution graphs. Then  $\mathcal{R}(G_s^{\text{init}}, G_t^{\text{init}}, \text{id}, t_1, t_2)$  holds.*

PROOF.  $\text{po}$ ,  $\text{rf}$ , and  $\text{mo}$  are empty in the initial graphs,  $\text{po}_{seq}$  is empty as well. Hence, the last three conditions of the simulation relation hold. The remaining ones are trivial for initial graphs.  $\square$

**Lemma 33.** *Let  $G_t$  and  $G_s$  be C20 consistent and assume  $\mathcal{R}(G_s, G_t, m, t_1, t_2)$  holds. If  $G_t \rightarrow G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \rightarrow^* G'_s$  and  $\mathcal{R}(G'_s, G'_t, m', t_1, t_2)$  also hold.*

PROOF. We do a case analysis on  $G_t \rightarrow G'_t$  and use Lemmas 34 and 35 to derive  $G'_s$  and  $\mathcal{R}(G'_s, G'_t, m, t_1, t_2)$ .  $\square$

**Lemma 34.** *Let  $G_t$  and  $G_s$  be C20 consistent and  $\mathcal{R}(G_s, G_t, m, t_1, t_2)$  holds. If  $G_t \xrightarrow[\text{exec}]{e} G'_t$  holds then there exists  $G'_s$  and  $m'$  such that  $G_s \xrightarrow[\text{exec}]{m'(e)} G'_s$  and  $\mathcal{R}(G'_s, G'_t, m', t_1, t_2)$  also hold.*

PROOF. Let us define  $e'$  as an event, s.t.  $\mathcal{P}_e(e')$  holds:

$$\mathcal{P}_e(e') \triangleq (G_s.\text{op}(e') = G_t.\text{op}(e) \wedge G_s.\text{loc}(e') = G_t.\text{loc}(e) \wedge G_s.\text{ord}(e') = G_t.\text{ord}(e))$$

Therefore, we can construct  $G'_s$  and  $m'$  as follows:

- $m' = m[e \mapsto e']$
- $G'_s.E = m' \uparrow G'_t.E$
- $G'_s.\text{lab} = G'_t.\text{lab} \circ m'$
- $G'_s.\text{rf} = m' \uparrow G'_t.\text{rf}$
- $G'_s.\text{mo} = m' \uparrow G'_t.\text{mo}$

For the last components, let us introduce  $c_t$ , such that  $c_t$  is the po-last event, appended before initial  $t_2$  events in  $G_t$ , and  $d_t$  is po-followed by  $c_t$ . Thread identifier function and program order are defined on case basis:

- (1) if  $\text{tid}(e) \neq t_2$  then
  - $G'_s.\text{tid} = G_s.\text{tid}[e \mapsto G'_t.\text{tid}(e)]$
  - $G'_s.\text{po} = m \uparrow G'_t.\text{po}$
- (2) if  $\text{tid}(e) = t_2$ :
  - $G'_s.\text{tid} = G_s.\text{tid}[e \mapsto t_2]$
  - $G'_s.\text{po} = m \uparrow G'_t.\text{po} \cup G_s.E_{t_1} \times \{e\}$

$\mathcal{R}(G_s, G_t, m, t_1, t_2)$  holds by construction. And consistency of  $G'_s$  follows from the consistency of  $G'_t$  due to monotonicity property Definition 18.  $\square$

**Lemma 35.** *Let  $G_t$  and  $G_s$  be C20 consistent and  $\mathcal{R}(G_s, G_t, m, t_1, t_2)$  holds. If  $G_t \xrightarrow[\text{re-exec}]{C} G'_t$  holds then there exists  $G'_s$ ,  $m'$ , and  $\text{rf}'_{re}$  such that  $G_s \xrightarrow[\text{re-exec}]{m' \uparrow C} G'_s$  holds, and  $\mathcal{R}(G'_s, G'_t, m', t_1, t_2)$  also holds.*

PROOF. We construct  $G'_s$  and  $m'$  as follows:

- $m' = \text{id}$
- $G'_s.E = m' \uparrow G'_t.E$
- $G'_s.\text{tid} = G_s.\text{tid}$

- $G'_s.\text{lab} = G'_t.\text{lab} \circ m'$
- $G'_s.\text{po} = G_s.\text{po}$
- $G'_s.\text{rf} = m' \uparrow G'_t.\text{rf}$
- $G'_s.\text{mo} = m' \uparrow G'_t.\text{mo}$

$\mathcal{R}(G'_s, G'_t, m', t_1, t_2)$  holds by construction.

Now, we set  $C_s$ ,  $\mathcal{D}_s$ ,  $f_s$ , and  $\leq_{\text{tid}_s}$  as follows:

- $C_s \triangleq m \uparrow C'_t$
- $\mathcal{D}_s \triangleq m \uparrow \mathcal{D}'_t$
- $f_s \triangleq \text{id}$
- $\leq_{\text{tid}_s} \triangleq \text{InsertBefore}(\leq_{\text{tid}_t}, t_1, t_2)$

The following properties follow immediately from the definitions:

- $C_s \subseteq G'_s.E$
- $\mathcal{D}_s \subseteq C_s$
- $\text{dom}(G.\text{po}; [\mathcal{D}_s]) \subseteq \mathcal{D}_s$
- $\text{WellFormed}(G|_{\mathcal{D}_s}, G'_s, C_s)$
- $\text{CommitEmbedded}(G_s, G'_s, C_s, f_s)$

The property  $\text{dom}(G'_s.\text{rpo}; [G'_s.E \setminus \mathcal{D}_s]) \subseteq \mathcal{D}_s$  follows from the fact that  $G'_s.\text{rpo} \subseteq G'_t.\text{rpo}$  and the respective property of the target graph.

To prove  $\text{ThreadOrderedUEvents}(G', C, <_{\text{tid}})$  we use the following observation:

$$\begin{aligned} G'_s.\text{vf}; G'_s.\text{=} ; [\mathcal{U}_s] &= [G'_s.W]; G'_s.\text{rf}^?; G'_s.\text{hb}^?; G'_s.\text{=} ; [\mathcal{U}_s] \subseteq \\ &\subseteq m' \uparrow ([G'_t.W]; G'_t.\text{rf}^?; G'_t.\text{hb}^?; G'_t.\text{=} ; [\mathcal{U}_t]) \subseteq \\ &\subseteq m' \uparrow \leq_{\text{tid}_t} \subseteq m' \leq_{\text{tid}_s} \end{aligned}$$

Consistency of the source graph,  $\text{Consistent}(\mathcal{M}, G'_s)$ , follows directly from the consistency of the target graph,  $\text{Consistent}(\mathcal{M}, G'_t)$ , due to monotonicity property Definition 18.

It is left to show that:

$$\langle G'_s, C_s \rangle \vdash G_s|_{\mathcal{D}_s} \Rightarrow^* G'_s$$

For this, we can apply Lemma 1 with  $\ell$  inherited from the target graph. □

## F XMC Model Checking

In this appendix we provide the proof of Theorem 4.1.

**PROOF.** We note that whenever XMC adds a new event in  $\text{porf}$  order following the basic procedure  $\text{VIST}(P, G)$  provided by GenMC [Kokologiannakis et al. 2022], it mimics the (Execute) rule of XMM—the soundness of this procedure is guaranteed by the GenMC itself.

We only need to show that application of the new procedure  $\text{REEXECUTE}(P, G)$  performed by the XMC is in fact a particular case of applying the (Re-Execute) of XMM. Remember that XMC selects the subsets of committed and determined events judiciously as follows:

$$\mathcal{D} \triangleq G.E \setminus \text{codom}[r]; G.\text{po}^? \quad \text{and} \quad C \triangleq \mathcal{D} \cup \text{codom}([r]; G.\text{po}^?) \cap \text{dom}(G.\text{rf} \setminus G.\text{po})$$

We will denote the fact that the procedure  $\text{REEXECUTE}(P, G)$  derives from a graph  $G$  new graph  $G'$  as  $G \xrightarrow[\text{xmc}]{\langle \mathcal{D}, C \rangle} G'$ . Also, let  $G_i \xrightarrow[\text{xmc}]{\langle e, \ell \rangle} G_{i+1}$  denote intermediate graph construction steps performed by  $\text{REEXECUTE}(P, G)$ , where  $e$  is an added event and  $\ell$  is its label.

Thus we need to show that  $G \xrightarrow[\text{xmc}]{\langle \mathcal{D}, C \rangle} G'$  implies  $G \xrightarrow[\text{re-exec}]{C} G'$ . This is true if the following properties hold:

- $WellFormed(G|_{\mathcal{D}}, G', C)$
- $WellFormed(G_{i+1}, G', C)$
- $CommitEmbedded(G, G', C, f)$
- $Consistent(G')$

Each of the above properties is proven to hold in Lemmas 37 to 40.  $\square$

**Lemma 36.** *Whenever XMC adds an event to a graph, the resulting graph is WellFormed.*

PROOF. XMC uses GenMC to add events to graphs. By design, GenMC ensures that the resulting graph is *WellFormed*. Since XMC starts from an empty graph, which is trivially *WellFormed*, all graphs explored by XMC and their prefixes are also *WellFormed*.  $\square$

**Lemma 37.** *If  $G \xrightarrow[xmc]{\langle \mathcal{D}, C \rangle} G'$ , then  $WellFormed(G|_{\mathcal{D}}, G', C)$ .*

PROOF. We show that  $WellFormed(G|_{\mathcal{D}}, G', C)$  holds by unfolding the definition of configuration well-formedness and showing that each of its conditions holds:

- $WellFormed(G|_{\mathcal{D}})$  follows from Lemma 36 because  $G|_{\mathcal{D}}$  is a prefix of  $G'$ .
- $\forall c \in C. G|_{\mathcal{D}}.tid(c) = G'.tid(c)$  because  $G|_{\mathcal{D}}$  is a prefix of  $G'$
- $\forall c \in C. G|_{\mathcal{D}}.lab(c) = G'.lab(c)$  because  $G|_{\mathcal{D}}$  is a prefix of  $G'$
- $[G|_{\mathcal{D}}.C]; G'.po; [G|_{\mathcal{D}}.C] \subseteq G|_{\mathcal{D}}.po$  because  $G|_{\mathcal{D}}$  is a prefix of  $G'$
- $[G|_{\mathcal{D}}.C]; G'.rf; [G|_{\mathcal{D}}.C] \subseteq G|_{\mathcal{D}}.rf$  because  $G|_{\mathcal{D}}$  is a prefix of  $G'$
- $[G|_{\mathcal{D}}.C]; G'.mo; [G|_{\mathcal{D}}.C] \subseteq G|_{\mathcal{D}}.mo$  because  $G|_{\mathcal{D}}$  is a prefix of  $G'$
- $G|_{\mathcal{D}}.R \subseteq \text{codom}(G|_{\mathcal{D}}.rf) \cup C$  because  $\mathcal{D} \subseteq C$
- $G'.R \cap C \subseteq \text{codom}([C]; G'.rf)$  because  $\mathcal{D} \subseteq C \wedge (\forall r \in G'.R \cap C. \text{dom}(G'.rf; r) \in \mathcal{D} \vee r \text{ is matched to a committed write})$

$\square$

**Lemma 38.** *If  $G_i \xrightarrow[xmc]{\langle e, \ell \rangle} G_{i+1}$ , then  $WellFormed(G_{i+1}, G', C)$ .*

PROOF. We show that  $WellFormed(G_{i+1}, G', C)$  holds by unfolding the configuration well-formedness definition and showing that each of its conditions holds:

- $WellFormed(G_{i+1})$  follows from Lemma 36 because  $G_{i+1}$  is a prefix of  $G'$ .
- $\forall c \in C. G_{i+1}.tid(c) = G'.tid(c)$  because  $G_{i+1}$  is a prefix of  $G'$ .
- $\forall c \in C. G_{i+1}.lab(c) = G'.lab(c)$  because  $G_{i+1}$  is a prefix of  $G'$ .
- $[G_{i+1}.C]; G'.po; [G_{i+1}.C] \subseteq G_{i+1}.po$  because  $G_{i+1}$  is a prefix of  $G'$ .
- $[G_{i+1}.C]; G'.rf; [G_{i+1}.C] \subseteq G_{i+1}.rf$  because  $G_{i+1}$  is a prefix of  $G'$ .
- $[G_{i+1}.C]; G'.mo; [G_{i+1}.C] \subseteq G_{i+1}.mo$  because  $G_{i+1}$  is a prefix of  $G'$ .
- $G_{i+1}.R \subseteq \text{codom}(G_{i+1}.rf) \cup C$  because, when a read  $r$  is added to  $G_i$  to obtain  $G_{i+1}$ , GenMC-XMM always creates an *rf* edge ending in  $r$ . Alternatively, if  $r$  was not added, it means that  $r \in \mathcal{D}$ , and thus  $r \in C$ .
- $G'.R \cap C \subseteq \text{codom}([C]; G'.rf)$  holds, as we showed in the proof of Lemma 37.

$\square$

**Lemma 39.** *If  $G \xrightarrow[xmc]{\langle \mathcal{D}, C \rangle} G'$ , then  $CommitEmbedded(G, G', C, f)$ .*

PROOF. We show that  $CommitEmbedded(G, G', C, f)$  holds by unfolding Definition 7 and showing that each of its conditions holds:

- $G|_{\mathcal{D}} \subseteq G$  by definition of the XMC restriction step.
- $G|_{\mathcal{D}} \subseteq G'$  by definition of the XMC restriction step.

- $f$  is injective, because only one write is matched to a  $R_\perp$ , so no two committed events in  $G$  can correspond to the same committed event in  $G'$ .
- $\forall c \in C. f(c) \neq \perp$  because if there are left-over  $R_\perp$  at the end of execution, XMC discards the graph.
- $\forall c \in C. G.\text{tid}(f(c)) = G'.\text{tid}(c)$  because either  $c \in G|_{\mathcal{D}}$ , or  $c$  is a write matched to a  $R_\perp$  that read from a write in  $G$  in the same thread as  $c$ .
- $\forall c \in C. G.\text{lab}(f(c)) = G'.\text{lab}(c)$  because either  $c \in G|_{\mathcal{D}}$ , or  $c$  is a write matched to a  $R_\perp$  that read from a write in  $G$  with the same label.
- $f \uparrow ([C]; G'.\text{rpo}; [C]) = [f \uparrow C]; G.\text{rpo}; [f \uparrow C]$  because we have added a specific check that discards executions that do not satisfy this condition.
- $f \uparrow ([C]; G'.\text{rf}; [C]) = [f \uparrow C]; G.\text{rf}; [f \uparrow C]$  because  $G|_{\mathcal{D}} \subseteq G'$  so all  $\text{rf}$  edges in  $G|_{\mathcal{D}}$  remain the same. Committed writes matched to a  $R_\perp$  in  $G'$  have an equivalent write in  $G$ , so their  $\text{rf}$  edges are also the same.
- $f \uparrow ([C]; G'.\text{mo}; [C]) = [f \uparrow C]; G.\text{mo}; [f \uparrow C]$  because we have added a specific check that discards executions that do not satisfy this condition.

□

**Lemma 40.** *If  $G \xrightarrow{xmc} G'$ , then  $\text{Consistent}(G')$ .*

PROOF. This is true, because by construction XMC checks the consistency of the resulting graph  $G'$  in the procedure  $\text{REEXECUTE}(P, G)$ . □

## G Benchmarks description

### Litmus tests.

- **LB+acq** is like the classic LB test, but the loads use acquire memory order.
- **LB+coh-cyc** is taken from [Chakraborty and Vafeiadis 2019]. In this example, the outcome  $r1 = 3 \wedge r2 = 2 \wedge r3 = 1$  is allowed by Promising, and forbidden by Weakestmo and XMM.
- **LB+equals** is a test where a compiler could potentially find invariant  $X = Y$ , and remove the redundant if statement if  $(X == Y)$ .
- **LB+rel** is like the classic LB test, but the stores use release memory order.
- **LB-invis-write+dep** is a test designed to verify that the execution obtained after applying the sequentialization optimization is outputted.
- **R-bot-multi-matching** is a test designed to verify that all writes that are compatible with a certain  $R_{bot}$  are matched.
- **java-test9a** is equal to Java causality test 9, taken from [Manson et al. 2005a], except that variable  $X$  is initialized to 2, and thread 3 writes 0 to  $X$  instead of 2.
- **LB+coh-cyc+Wd** is similar to **LB+coh-cyc**, but with a read from a distinct location in the second thread and a write to this location in a separate thread.  $r1 = 3 \wedge r2 = 2 \wedge r3 = 1$  should be still forbidden.
- **java-test10** is Java causality test 10 [Manson et al. 2005a]. The Java model forbids outcome  $r1 = 1 \wedge r2 = 1 \wedge r3 = 0$ , but it is allowed by XMM.
- **java-test19** is Java causality test 19 [Manson et al. 2005a]. Both the Java model, and XMM allow outcome  $r1 = 42 \wedge r2 = 42 \wedge r3 = 42$ .
- **java-test20** is Java causality test 20 [Manson et al. 2005a]. Both the Java model, and XMM allow outcome  $r1 = 42 \wedge r2 = 42 \wedge r3 = 42$ .
- **LB+seq** is a test taken from the Promising paper [Kang et al. 2017]. It tests whether the sequentialization optimization is allowed.

- **java-test5** is Java causality test 5 [Manson et al. 2005a]. The Java model forbids outcome  $r1 = 1 \wedge r2 = 1 \wedge r3 == 0$ , but XMM allows it.
- **LB+coh+RR+cf** this test shows between the global **mo** order of the Weakestmo model, and the absence of such constraint in the XMM model. Due to the absence of this constraint, XMM allows more executions than Weakestmo in this test.

### Data Structure Benchmarks.

- **mpmc-queue-bnd** is a multi-producer multi-consumer queue.
- **ticketlock** is an implementation of a ticketlock algorithm.
- **chase-lev** is a dynamic circular work-stealing deque
- **buf-ring** is a multi-producer multi-consumer ring buffer.
- **dq** is a multi-producer multi-consumer deque.
- **stc** is a stack implementation using Treiber's algorithm.
- **linuxrwlocks** is a read-write lock ported from the Linux kernel
- **twalock** is a ticket lock augmented with a waiting array
- **fcombiner** implements concurrent access to a set data structure using the flat combiner access paradigm.
- **mutex** is a mutual exclusive lock.

### Synthetic Benchmarks.

- **reorder2**: 2 threads write to 2 variables, while 2 other threads read from them.
- **fib-bench**: 2 threads compute the Fibonacci sequence using two shared variables.
- **szymanski**: is an implementation of Szymański's Mutual Exclusion Algorithm.
- **dekker-bnd**: is an implementation of Dekker's Mutual Exclusion algorithm.
- **indexer**:  $N$  threads modify a shared array.
- **ainc**:  $N$  threads increment a shared variable by 1.
- **casrot**:  $N$  threads compare-and-swap a shared variable, rotating its value.
- **casw**:  $N$  threads compare-and-swap a shared variable, and write a new value to it.

### Load Buffering Benchmarks.

- **LBn+ctrl**:  $N$  threads with a load buffering pattern spanning through all threads. All threads except the first one have a real control dependency between the load and the store.
- **LBn+data**:  $N$  threads with a load buffering pattern spanning through all threads. All threads except the first one have a real data dependency between the load and the store.
- **LBn**:  $N$  threads with a load buffering pattern spanning through all threads.
- **LBn-pairs**:  $N$  threads divided in pairs. Each pair reads/writes from/to a unique pair of variables forming a load-buffering race.

## G.1 Duplicate Executions

In Table 3 we show the benchmarks with the respective executions in the model checkers and the number of duplicate executions in WMC and XMC. We also note the number of LB races. In Table 4 we note the execution times of the model checkers to explore these executions.

Table 3. Load Buffering benchmarks. XMC finds the same number of cyclic executions as other tools. The number of duplicates visited is slightly less than that of WMC.

Test Name	Number of Executions				Number of Duplicates		LB Races
	GenMC	HMC	WMC	XMC	WMC	XMC	
LBN+ctrl(10)	9	11	11	11	0	1	1
LBN+ctrl(12)	10	11	11	11	0	1	1
LBN+ctrl(14)	10	11	11	11	0	1	1
LBN+data(10)	19	1024	1024	1024	0	1	10
LBN+data(12)	1023	1024	1024	1024	0	1	10
LBN+data(14)	1023	1024	1024	1024	0	1	10
LBN(10)	1023	1024	1024	1024	9	10	10
LBN(12)	4095	4096	4096	4096	11	12	12
LBN(14)	16383	16384	16384	16384	13	14	14
LBN-pairs(10)	243	1024	1024	1024	2101	2184	2560
LBN-pairs(12)	729	4096	4096	4096	11529	10379	12288
LBN-pairs(14)	2187	16384	16384	16384	61741	48250	57344

Table 4. Load Buffering time benchmarks. XMC takes the same time as other tools when there are few LB races. It takes longer when the number of LB races increases.

Test Name	Execution Time				
	GenMC	HMC	WMC	XMC	LB Races
LBN+ctrl(10)	0.06s	0.05s	0.01s	0.04s	1
LBN+ctrl(12)	0.05s	0.04s	0.01s	0.04s	1
LBN+ctrl(14)	0.04s	0.04s	0.01s	0.05s	1
LBN+data(10)	0.04s	0.19s	0.10s	0.15s	10
LBN+data(12)	0.10s	0.18s	0.10s	0.13s	10
LBN+data(14)	0.11s	0.17s	0.10s	0.11s	10
LBN(10)	0.11s	0.14s	0.12s	0.13s	10
LBN(12)	0.33s	0.55s	0.46s	0.40s	12
LBN(14)	1.37s	2.40s	1.68s	1.47s	14
LBN-pairs(10)	0.06s	0.19s	0.34s	1.43s	2560
LBN-pairs(12)	0.12s	0.65s	2.27s	7.06s	12288
LBN-pairs(14)	0.34s	3.19s	11.60s	38.12s	57344
